Phenylhydroxylamine. $C_6H_5.NH.OH$.—This substance has no known application to the treatment of disease, but requires notice on account of the occasional poisoning by it of those who are engaged in the manufacture of certain chemicals. For cases, see Hirsch and Edel (*B. K. W.*, xxxii, 1895), L. Lewin (*A. E. P. P.*, Bd. xxxv.). The symptoms, which have developed with great suddenness, have consisted of coma, cyanosis, pulselessness, abolition of corneal and pupillary reflexes, chocolate-colored blood, methemoglobinuria, grayish-blue lips, and intense blue-red surface of limbs. The treatment of these cases should consist in active artificial respiration; together with hypodermic injections of strychnine and of digitalis. For the action of phenylhydroxylamine upon the blood, see L. Lewin (*A. E. P. P.*, Bd. xxxv.).

Phenyl-boric Acid. *Acidum Phenyl-boricum.* $C_6H_5.B(OH)_2$.—A white powder, soluble with difficulty in cold water, which was found by G. Molinari (*Chem. Ob.*, 1892, ii, 224) to be a powerful germicide, checking putrefaction in 0.75 per cent. solution, and being very poisonous to the cholera and other pathogenetic bacilli. It is said to act especially well locally upon venereal

ulcers, and to be less poisonous than phenol. The fatal dose for the rabbit is fixed at twenty-three grains (1.5 Gm.).

Phenyl-salicylic Acid. *Acidum Phenyl-salicylicum.* *Oxydiphenylcarbonic Acid.* *Ortho-oxydi-phenyl-carboxylic Acid.* $C_6H_5(OH)(C_6H_5)COOH$.—A whitish powder, soluble in water with difficulty, easily soluble in alcohol, ether, and glycerin; which, according to F. Bock (*In. Dis.*, Berlin, 1892), is about equivalent in germicidal properties to salicylic acid. Its salts are said to be less poisonous than are those of salicylic acid. It is made by subjecting a mixture of calcium benzoate and salicylate to dry distillation and fusing the product with potassium hydroxide. It is used as an antiseptic dusting powder.

Phenylurethane. *Euphorin.* *Ethyl Phenylcarbamate.* *Carbamile Ether.*

$C_6H_5O_2H_{11}N.(CO \begin{Bmatrix} OC_2H_5 \\ NH(C_6H_5) \end{Bmatrix})$. This is a white crystalline substance, which is made by the action of ethyl chloroformate (or ethylic ether) on aniline. It is almost insoluble in cold water, very soluble in boiling water, alcohol, and ether, and melts at $51^\circ C.$ ($123.8^\circ F.$). It has been physiologically investigated by Giacoasa, who finds that its 2 per cent. solution very distinctly hinders or altogether arrests the growth of bacteria and bacilli; that in the frog it produces a general paralysis due to an action upon the nerve centres; that in the rabbit it causes somnolence, hebetude, albuminuria, gastritis, etc.; but very large doses are required to have any effect, over three hundred grains having been given to a dog without producing inconvenience. It does not form methemoglobin in the blood. After its ingestion about 8 per cent. of it was found in the urine in the form of *oxyphenylurethane* in combination with sulphuric acid. It has been used by Sansoni, Giacomini, and Adler, as an antipyretic and antirheumatic, also as an analgesic. It has also been employed as an antiseptic dressing in various ulcerations, as a substitute for iodoform. (*B. G. T.*, Jan. 1892.) Dose, eight to fifteen grains (0.5–1.0 Gm.).

Phesin. *Acet-p-phenetidine-sodium sulphonate.*

$C_6H_5 \begin{Bmatrix} O-C_2H_5 \\ SO_2Na \\ NH-CO-CH_3 \end{Bmatrix}$. Phesin is a sulphonic

derivative of phenacetin, and occurs as a reddish-brown, amorphous, tasteless powder, having a slightly irritant salt taste, very soluble in water, affording a Bismarck-brown solution of acid reaction. It has been studied by Von Vámosy and Fenyvessy (*Th. M.*, 1897), who find that it resembles phenacetin very closely in its action, but is characterized by the promptness and shortness of its influence.

Phlorizin. *Phloridzin.* *Phlorrhizin.* $C_{21}H_{24}O_{10} + 2H_2O$.—This is a bitter principle, discovered by De Koninck of Germany, in the bark of the apple, pear, cherry, and plum trees. It is most abundant in the bark of the root, and derived its name from this circumstance (from two Greek words, *φλοιός*, bark, and *ρίζα*, a root). It is light, white, crystallizable in silky needles, of a bitter taste, soluble in about 1000 parts of cold and in all proportions in boiling water, very soluble in alcohol and methyl alcohol, scarcely soluble in ether, cold or hot, dissolved without change by solutions of the alkalis, deprived of its water of crystallization at $100^\circ C.$ ($212^\circ F.$), and fusible at a somewhat higher temperature. The ammo-

niacal solution becomes red on exposure to the air on account of the formation of *phlorizein*, $C_{21}H_{30}N_2O_{18}$. Phlorizin is without acid or alkaline reaction, and belongs to the class of glucosides. When heated with diluted hydrochloric or sulphuric acid, it is converted into sugar and a peculiar substance called *phloreizin*, $C_{15}H_{14}O_5$. (See *Chem. Gaz.*, viii. 392.) To obtain phlorizin, the fresh bark of the root of the apple tree should be selected, as the dried bark is said to contain it in much smaller proportion. The bark is to be boiled for an hour or two successively in two separate portions of water, each sufficient to cover it, and the decoction set aside. At the end of thirty hours they will have deposited a considerable quantity of colored phlorizin, which may be purified by boiling for a few minutes with distilled water and animal charcoal, filtering, repeating this process two or three times, and then allowing the solution to cool slowly. The phlorizin is deposited in the crystalline state. An additional quantity may be obtained by evaporating the decoction to one-fifth of its bulk, allowing it to cool, and purifying the substance deposited in the same manner as before. Rochleder states that the leaves contain a principle, *isophlorizin*, isomeric with phlorizin.

Phlorizin is physiologically quite inactive, but when given to the lower animals in very large doses (from seven to ten grains to the pound), it produces great polyuria, with the elimination of large amounts of sugar, emaciation, polydipsia, and other symptoms of diabetes, with chronic nephritis. (See Coolen, *Archiv. de Pharmacod.*, vol. ii. 1896; also Kossa, *Z. f. B.*, xl. 1900.) Although at one time recommended as an *antiperiodic* in doses of from ten to fifteen grains (0.65–1.0 Gm.), it is of no use in practical medicine except as a test for renal insufficiency. In the *phlorizin test*, five to ten milligrammes of phlorizin are added to a sterilized solution containing an equal quantity of sodium carbonate, and given subcutaneously, the bladder having been emptied just before administration. If the kidney be normal, sugar should appear in the urine half an hour later; if there be no excretion, or if the excretion of sugar be delayed, the renal function is considered to be insufficient. (*Boston City Hospital Report*, 1902.)

Phosphine. *Diamidophenylacridine Binirate.* This is a reddish powder, a solution of which in alkaline fluid is phosphorescent. Notwithstanding its commercial name, it contains no phosphorus and should not be confounded with the definite chemical substance, phosphine, PH_3 . It has been asserted to be a valuable analgesic, but Dujardin-Beaumetz finds phosphine too irritant to the stomach for practical use. (*G. H. M. C.*, June, 1888.)

Phosphorescent Powder or Paint.—Made by mixing calcined oyster shells, 100 parts; caustic lime, 100 parts; calcined sodium chloride 25 parts; then incorporate about 55 parts of sulphur and from 8 to 18 parts of calcium, barium, strontium or magnesium sulphide. It may be used as a paint by mixing it with varnish. If the substance has been exposed to sunlight, it becomes luminous in the dark. *Canton's phosphorus* consists of 2 parts of oyster shells and 1 part of sulphur.

Photoxylon.—This is a nitro-cellulose, which is said to be entirely soluble in a mixture of equal parts of concentrated ether and alcohol. According to Beringer, a 3 per cent. solution leaves on evaporation a very tough collodion-like film. Pho-

toxylon is made from wood pulp, by methods of nitration similar to those given under pyroxylin, which is its chemical counterpart.

Phyllanthus. *Phyllanthus Niuri*, L.—Ottow isolated from this widely distributed euphorbiaceous plant *phyllanthin*, $C_{30}H_{37}O_8$, which crystallizes in colorless needles, is intensely bitter, insoluble in water, but soluble in alcohol, petroleum benzin, chloroform, and ether.

Physalis. *Physalis Alkekengi*, L. *Alkekengi*. Common Winter Cherry. *Alkekengi*, *Coqueret*, Fr. *Judenkirsche*, *Schlutte*, G.—A perennial herbaceous plant, belonging to the Solanaceae, growing wild in the south of Europe, and cultivated in our gardens. The fruit is a round red berry, about as large as a cherry, enclosed in the inflated calyx, and containing numerous flat kidney-shaped seeds. All parts of the plant are bitter, especially the leaves and the capsules enveloping the fruit. The berries are very juicy, and have an acidulous, bitterish taste. By drying they shrink, and become of a brownish-red color. The bitter principle, *physalin*, has been isolated by Dessaignes and Chautard. It is obtained by agitating an infusion of the plant with chloroform, which extracts the bitter principle, and yields it on evaporation. To purify it, dissolve it in hot alcohol, add a little animal charcoal, filter, precipitate by water, and wash the precipitate with the same liquid. It is a light powder, white with a shade of yellow, of a taste slight at first, but in the end permanently bitter, very slightly soluble in cold water, somewhat more soluble in boiling water, and freely soluble in alcohol and chloroform, especially with the aid of heat. Its composition is $C_{14}H_{16}O_5$. (*J. P. C.*, 3e sér., xxi. 24.) The berries are said to be aperient and diuretic, and have been recommended in suppression of urine, gravel, and other diseases of the urinary passages. Gendron recommends them very highly as a febrifuge. (*A. G. M.*, xxiii. 536.) They also have been highly commended in gout. (*Braithwaite's Retrospect*, Am. ed., No. 46, 214.) From six to twelve berries, or half an ounce of the expressed juice, may be taken for a dose; and much larger quantities are not injurious. They are consumed to a considerable extent in some parts of Europe as food. The berries of *Physalis viscosa*, L., of this country, are said by Clayton to be remarkably diuretic.

Phytelephas.—*Phytelephas macrocarpa*, Ruiz. and Pav., or *negrito-palm*, of Ecuador, yields the *Tagú nut*, from which is derived the hard white substance, *vegetable ivory* or *corajo*. The nuts contain a fixed oil which is said to enter commerce. (*J. P. C.*, xvi.)

Phytolacca acinosa, Roxb. (Fam. Phytolaccaceae).—This plant has long been used in Japan as a diuretic, and is said to be violently poisonous. C. Nagai has separated from it an amorphous resin, *phytolaccotoxin*, which appears to be a spinal convulsant, and at the same time stimulant to the circulation, probably through the vasomotor centres. (*Sei-kwai Med. Journ.*, April, 1891.)

Pichurim Beans. *Sassafras Nuts*. *Fèves Pichurim*, *Noix de Sassafras*, Fr. *Pichurim-bökn*, *Sassafrasnüsse*, G.—The seeds of *Nectandra Puchury-major*, Nees (*Ocotea Puchury-major*, Mart.), and *N. Puchury-minor*, Nees (*O. Puchury-minor*, Mart.) (Fam. Lauraceae), yielding respectively "*Fabæ Pichurim majores*" and "*Fabæ Pichurim minores*." The two species are closely allied and both have been known to botanists as *Ocotea Pichurim*, H. B. K. (*Laurus Pichurim*,

Willd.). The trees grow in Brazil, Guiana, Venezuela, and other parts of South America, and are sometimes spoken of as *Brazilian* or *South American Sassafras*. Carson of the University of Pennsylvania, had specimens of the fruit and other parts of the trees sent him, sufficient to verify the ascription of the pichurim beans to this source. (*A. J. P.*, xxvii. 385.) The beans are the kernels of the fruit separated into halves. They are ovate-oblong or elliptical, flat on one side, convex on the other, of a grayish-brown color externally, chocolate-colored within, of an aromatic odor between that of nutmegs and sassafras, and of a spicy pungent taste. There are two kinds, one about an inch and a half long by half an inch in breadth, the other little more than half as large, rounder, and of a dark brown color. The former were said by Carson to come from Brazil, the latter from Venezuela, being derived respectively from the two species mentioned above. (*Ibid.*, 387.) Bonastre has found them to contain a concrete volatile oil, a fatty matter of the consistence of butter, stearin, resin, brown coloring matter, fecula, gum, sugar, and lignin. Their virtues depend on the volatile oil. The buttery portion, known as *pichurim fat*, amounting to about 30 per cent., contains *laurostearin*, $C_{35}H_{55}O_2$, and *pichurim camphor*, which, according to Gerhardt, is identical with laurel camphor. In *A. J. P.*, 1851, 1, Procter described a liquid product brought from South America, known as the *native oil of laurel* or *sassafras*, or *acete de sassafras*, said to be obtained by making incisions in the trunk of a tree growing on the Orinoco. As described by Procter, it is an oleoresin, of the sp. gr. 0.898, of a light auburn color, a peculiar penetrating odor, and an aromatic, bitterish, pungent, and somewhat camphorous taste. On distillation, almost the whole passes over in the shape of a colorless volatile oil, a small proportion only of resinous matter being left behind. This oleoresin is conjectured to be the same as that employed for adulterating the copaiba exported from Maracaibo. It may be distinguished from copaiba by its ready solubility in alcohol of 0.838, and by the fact that its volatile oil is acted on by potassium. It is believed to be the same product as the "native oil of laurel" described by Pereira, which was obtained from Demerara, and by incisions in a large tree. Carson, on comparing it with a specimen of oil presented to him as obtained from the same tree with the fruit mentioned, had no hesitation in considering them as identical, and, therefore, in referring the so-called native oil of laurel to *Nectandra Puchury*. Müller, by distilling the oil in contact with sulphuric acid, obtained a greenish-yellow oil possessing the peculiar odor of the beans. By fractional distillation he separated—1, a colorless oil, boiling at 150° C. (302° F.); 2, a colorless oil, boiling between 165° C. (329° F.) and 170° C. (338° F.); both of these oils consisting principally of hydrocarbons, $C_{10}H_{16}$; 3, a greenish-yellow viscid oil, boiling between 235° C. (455° F.) and 240° C. (464° F.), and having the composition $C_{35}H_{55}O_2$; 4, a deep blue oil, having a faint odor, boiling between 260° C. (500° F.) and 265° C. (509° F.). In medicinal properties the pichurim beans resemble the common aromatics, and may be employed for the same purposes. In South America they are said to be used as a substitute for nutmeg, and have even been called by that name. They are rare in this country. The oil obtained from the tree is said

to impart its odor to the perspiration and urine, and to be useful in *rheumatism*, *gout*, etc. The bark is sometimes employed as a tonic and febrifuge.

Picrasma. *Picrasma quassioides* (Ham.), Benn. (Fam. Simarubaceæ).—The wood of this tree, which grows in the subtropical Himalayas, and resembles closely the *Ailanthus* in its appearance, has an intensely bitter taste, and has been proposed as a substitute for quassia. W. Dymock and C. J. H. Warden have found in it a crystalline principle which they believe to be quassin, and to exist in the probable proportion of from 0.02 to 0.03 per cent. The same investigators believe that the drug has in it a peculiar alkaloid. (*P. J.*, xx, 1889.) A principle analogous to quassin was isolated by Shimoyama from the bark of *P. eilantoides*. (*Ap. Ztg.*, 1892, 439.)

Picric Acid. *Acidum Picricum.* *Carbazotic Acid.* *Trinitrophenol.* *Nitrophenic Acid.* $C_6H_3(NO_2)_3.OH$.—This acid is obtained by the action of nitric acid on indigo, silk, leather, wool, aloes, benzoin, Australian gum, and other substances, or, as the name indicates, from phenol (carbolic acid). It may be cheaply prepared by adding coal tar creosote (impure phenol) gradually to strong nitric acid and heating, when, on standing, the picric acid will crystallize out; but in practice it is now almost always made by dissolving crystallized phenol in strong sulphuric acid, and adding either nitric acid or sodium nitrate to the resultant phenolsulphonic acid. It is in pale yellow shining scales, fusing at $122.5^\circ C.$ ($252^\circ F.$) and subliming undecomposed. It is soluble in water, to which it gives a strong yellow color and very bitter taste. Its salts crystallize readily, and explode when heated. The potassium salt is so sparingly soluble that an alcoholic solution of the acid may be used as a test for this alkali. It is largely used in dyeing, producing magnificent yellow colors, and, in connection with indigo or Prussian blue, different shades of green. The salts which picric acid forms with potassium and sodium are yellow and bitter, and are much used in the arts. They are, however, violent explosives, and as such have produced very serious consequences. A saturated aqueous solution of picric acid is a very delicate test for albumin. *Ammonium picrate* is universally preferred for use in medicine. It crystallizes in rhombic scales, which are somewhat more soluble than the corresponding potassium salt. It is explosive when heated or struck.

Picric acid and its salts, when in sufficient dose, are poisonous both to man and to the lower animals, though a teaspoonful of ammonium picrate has been taken without the production of other symptoms than those of gastro-intestinal irritation. Toxic doses in the lower animals stain the tissues, and produce falling temperature, weakness, diarrhæa, collapse, convulsions, and death; in man six and one-half drachms (25.2 Gm.) have caused leucocytosis, intense yellow color of nails, skin, and cornea with violent vomiting, and purging and collapse, followed by recovery. (*W. M. P.*, 1900.) According to Erb, picric acid changes the color of the blood, increases the number of the white corpuscles, and so alters the red blood disks as to produce the appearance of nucleation. Picric acid is a very feeble germicide. The ammonium salt has been used to a considerable extent in *malarial diseases* and in *trichiniasis*. Experience, however, has shown that it has no value in the latter disorder, and is of very little impor-

tance as an antiperiodic. The local application of the solution (from 8 per cent. to saturation) of picric acid has been strongly recommended by various surgeons in the treatment of *burns*. In some cases it causes a great deal of pain, and in a number of instances, especially children, it has produced by its absorption, vomiting, purging, jaundice, and other symptoms of poisoning. The 1 per cent. solution is sometimes used to harden the feet of soldiers and pedestrians, also in *erysipelas*, *eczema*, *seborrhœa*, and parasitic diseases of the skin and hair. The dose of ammonium picrate, in pill, is half a grain (0.032 Gm.), three times a day; though Erb affirms that from nine to fifteen grains (0.6–1.0 Gm.) may be given in a day without danger.

Ferric Picrate may be prepared by digesting pure crystallized picric acid with an excess of recently precipitated ferric oxide and water at a gentle heat, till the acid has disappeared, filtering, and evaporating the filtrate at a temperature not exceeding $100^\circ C.$ ($212^\circ F.$). Thus prepared it is amorphous, reddish brown in mass, lighter colored in powder, of an astringent and intensely bitter and persistent taste, and readily soluble in water. On account of its bitterness it is best given in pill. (*A. J. P.*, 1862.)

Picrol. *Di-iodo-resorcin-potassium Monosulphonate.* $C_6H_2(OH)_2SO_3K$.—This antiseptic contains about 52 per cent. of iodine. It occurs in colorless and odorless crystals having a very bitter taste, soluble in water, glycerin, and ether. It is used as a substitute for iodoform and corrosive sublimate.

Picrorhiza. *Br. Add.*—Under the name of *kutki* or *katti* there has long been used in India a rhizome which has been frequently spoken of by European and Mahometan writers as *black hellebore*, but is essentially different. It is the dried rhizome of an Alpine-Himalayan plant, *Picrorhiza Kurroa*, Royle (Fam. Scrophulariaceæ.) From this rhizome H. Warden has separated a glucoside, *picrorhizin*, which is freely soluble in water and alcohol and appears to be the bitter principle of the drug; also a red-brown, resinous, tasteless body, *picrorhizetin*, and, perhaps, cathartic acid (*Pharmacog. Indica*, vol. 3). The natives of India attribute active antiperiodic power to picrorhiza, which appears to be a powerful bitter tonic with slight laxative action. It is given in doses of from one to twenty grains (0.065–1.3 Gm.) as a tonic and from forty to fifty grains (2.6–3.2 Gm.) as an antiperiodic, usually in combination with aromatic.

The *Br. Add.* recognizes the *liquid extract* (*Extractum Picrorhizæ Liquidum*, *Br. Add.*), dose, twenty to sixty minims (1.3–3.75 Cc.); and a *tincture* (*Tinctura Picrorhizæ*, *Br. Add.*), two and one-half ounces to a pint (77.7 Gm. to 473 Cc.); dose, one-half to one fluidrachm (1.3–3.75 Cc.).

Pimpinella. *Pimpinella Saxifraga*, L. *Small Burnet Saxifrage.* *Saxifraga.* *Radix Pimpinellæ*, P. G. *Grand Boucage*, Fr. *Pimpinell*, *Bibernell*, G. A perennial umbelliferous European plant, growing on sunny hills, and in dry meadows and pastures. The root has a strong, aromatic, yet unpleasant odor, and a sweetish, pungent, biting, aromatic, bitterish taste. Its active constituents are volatile oil and an acid resin. The volatile oil is described as a golden-yellow, limpid liquid, lighter than water, of penetrating odor recalling parsley, and of biting taste. Buchheim obtained from the alcoholic extract an active principle, which he called *pimpinellin*, insoluble in water and petro-

leum ether, but soluble in alcohol. It is considered diaphoretic, diuretic, and stomachic, and has been used in *chronic catarrh, asthma, dropsy, amenorrhæa*, etc. The dose in substance is about half a drachm (2.0 Gm.), and in infusion two drachms (7.7 Gm.). The root is used also as a local stimulant in toothache, etc.

Pinckneya. *Pinckneya pubens*, Michx. *Fever tree*. (Fam. Rubiaceæ.)—A large shrub or small tree, growing in South Carolina, Georgia, and Florida, in low and moist places along the seacoast. It is botanically allied to the *Cinchonæ*. The bark is bitter and has been used with alleged advantage in *intermittent fever*. E. H. Naudain (A. J. P., April, 1885) found in it a glucoside, *pinckneyin*, but no alkaloid.

Pineapple. *Ananas sativa*, Schult. f. (*Ananassa sativa*, Lindl., *Bromelia Ananas*, L.) (Fam. Bromeliaceæ.)—Some years ago V. Marcano discovered that the juice of the ordinary pineapple has the power of digesting proteid vegetable and animal substances. R. H. Chittenden (Trans. Connecticut Academy, vol. viii. 1891) found that the fresh pineapple juice is a very constant and powerful digestant of albuminous matters; that the ferment is decidedly active in the presence of either acids or alkaline carbonates, but is most energetic in neutral solution; that the ferment is most active between 50° and 60° C. (122° and 140° F.); still digests at 30° C. (86° F.), but is destroyed at a temperature of 70° C. (158° F.); that the digestion takes place with rapidity; that the ferment, to which the name *bromelin* has been given, is more nearly related to trypsin than to pepsin, forming during its action not only proteoses and peptone, but also leucine and tyrosine.

Piper Novæ-Hollandæ, Miq. (Fam. Piperaceæ.)—The berries of this Australian pepper contain a volatile oil, and are said to be useful in *gonorrhæa* and allied diseases.

Piper ovatum, Vahl.—From the leaves of this plant, found growing in Trinidad, Dunstan and Carr (Chem. News, 1895, 278) extracted a crystalline principle, *piperovatine*, $C_{14}H_{21}NO_2$. It is insoluble in water, but soluble in alcohol. It is said to act as a depressant of both motor and sensory nerves, and as a stimulant to the spinal cord.

Piperazine. *Arthriticine*. *Diethylenediamine*. $Na_2 \left\{ \begin{matrix} H_2 \\ (C_2H_4)_2 \end{matrix} \right\}$. This is formed by the action of ammonia upon ethylene bromide or chloride. A mixture of bases from this reaction is fractionated, and from the fraction boiling between 130° and 180° C. (266°–356° F.), the diethylenediamine separates on cooling. It forms glassy lustrous tables, melting at from 104° to 107° C. (219.2°–224.6° F.), and boils at 145° C. (293° F.). Both the free base and the hydrochloride are very soluble in water. The latter crystallizes in silky, lustrous, lanceolate forms. Piperazine has an alkaline taste and reaction and a weak but characteristic odor. It is very soluble in water and slightly less so in alcohol. In experiments made by Bock upon rabbits, no evidences of stimulating properties could be obtained. The blood pressure was never increased, but if the dose were large enough was temporarily depressed. In a cold aqueous solution it is said to dissolve twelve times as much uric acid as will lithium carbonate, and one part of uric acid and piperazine dissolves in fifty parts of water, while lithium urate requires three hundred and sixty-eight times its own weight to dissolve it.

Outside of the body, piperazine acts as a powerful solvent of uric acid; not only when the acid is pulverulent, but also when it is in the form of hard calculi. It was also found by J. H. Brik of Vienna, that even when the calculi are largely composed of other materials they are broken up by the piperazine affecting the uric acid in them. As piperazine seems in ordinary doses without marked general influence upon the system, and as it does not irritate the mucous membranes of the gastro-intestinal or genito-urinary tract, it would appear to be a very valuable remedy in the treatment of *uric acid gravel and calculi*. Van der Klip, as the result of a carefully conducted series of experiments, denies, however, that piperazine is as powerful a solvent of uric acid as is the lithium carbonate. In regard to the action of piperazine upon the system, Van der Klip has found that in the lower animals, in sufficient dose, it produces vomiting, irregular breathing, general muscular weakness, and relaxation; that it also decreases the coagulability of the blood, and has power in checking the action of peptonizing ferments. He further states that it decreases the evolution of oxygen by oxyhæmoglobin. How far piperazine will prove to be of value in uric acid diathesis remains at present uncertain, although the results so far are, on the whole, encouraging. Umphenbach found it to be a powerful diuretic and even recommends it in *dropsies*. Vogt (Soc. Thérap., 1891) affirms, as the result of his investigations, that in doses of fifteen grains (1.0 Gm.) a day it produced a diminution both of the relative and absolute quantity of uric acid. On the other hand, Ebstein and Sprague found that the drug did not affect either the absolute or relative excretion of urea or of uric acid. There is much clinical testimony as to the value of the remedy in *gout and rheumatism*, and certainly in those cases in which deposition of urates has occurred the remedy should have a thorough trial. H. C. Wood has found it to act very well in some cases and fail entirely in others. In *stone*, injections of piperazine into the bladder are also worthy of trial. The injection of small doses of piperazine immediately into gouty joints may be essayed. During the taking of piperazine the urine usually is reddish brown, and the drug can be readily obtained from the urine by methods which are detailed in N. R., 1892. Piperazine may be given in the hypodermic injection of a 2 per cent. solution, which is said to produce some pain but no abscesses; or, better, fifteen grains (1.0 Gm.) of it may be administered during the day in a quart of plain or carbonated water. It is so hygroscopic that it cannot well be given in pill or powder.

Pipi Root.—The root of the *Petiveria hexaglochis*, Fisch. and Mey. (Fam. Phytolaccaceæ), which more than sixty years ago attracted notice in Europe, is said to have re-entered commerce. It is described as consisting of irregularly bent pieces, 3 to 6 Mm. thick, externally grey brown, upon transverse section showing a brownish bark with white dots, and a lighter colored radiating ligneous cord. The cork-layer consists of 3 or 4 rows of cells, the thick primary bark encloses crystals of calcium oxalate; the woody cord contains tracheids with narrow dotted ducts, two-rowed medullary rays and in the centre a thin pith. The genus *Petiveria* is confined to tropical America and the shrubby plants are mostly acid and have an alliaceous odor. It is reported to be a stimulant, expectorant and diaphoretic. (A. J. P., Aug. 1887.)

Piscidia. *Piscidia Erythrina*, L. *Jamaica Dogwood*.—This is a leguminous tree growing throughout the West Indies, and yielding to commerce a very valuable wood. From time immemorial the bark has been used for catching fish. The leaves, twigs, and root bark are collected, macerated with the residue from the distillation of rum or with lime water, then transferred into baskets, and the latter dragged up and down the water until the fish are stupefied.

In 1844 William Hamilton called the attention of the profession to the plant (*P. J.*, Aug. 1844) as a powerful narcotic and analgesic. The bark of commerce is "in pieces of from two to four inches in length, and from one to two inches wide, and about one-eighth of an inch in thickness. The outer surface of some of the pieces is of a dark gray-brown, while others are of a yellow-brown, with no shade of gray present. The bark is frequently studded with flattened protuberances of a lighter color than the surrounding cork. The central part of the bark is much lighter colored, and, when wet or freshly broken, is of a peculiar blue-green color. The inner part of the bark is of a dark brown color and very fibrous. It has a strong disagreeable odor of opium when broken into pieces. It is acrimonious, and produces a burning sensation in the mouth and pharynx."

E. Hart obtained a neutral principle, $C_{25}H_{24}O_8$, to which he gave the name *piscidin*. When purified by crystallization from alcohol it was obtained in colorless crystals, fusing at 192° C. (377.6° F.), insoluble in water, slightly soluble in ether, easily soluble in benzene, chloroform, and boiling alcohol. (*A. J. P.*, 1883, 369. See also *Ibid.*, Sept. 1898.) Paul C. Freer and A. M. Clover have examined Hart's piscidin and found it to consist of two distinct chemical compounds. The first of these forms colorless, highly refracting rectangular prisms, melting at 201° C. (393.8° F.); composition $C_{23}H_{20}O_7$. It is soluble in chloroform, moderately soluble in benzene and in acetic acid, sparingly so in alcohol; insoluble in ether, ligroin, and in alkaline solutions. The second separates from alcohol in fine yellow needles, melting at 216° C. (420.8° F.); composition $C_{22}H_{18}O_6$. It is soluble in benzene and chloroform, sparingly so in ether; insoluble in ligroin. The authors found also in the aqueous extract of the bark *piscidic acid*, soluble in water; insoluble in chloroform, benzene or ligroin. It forms acicular crystals, which melt at 182° to 185° C. (359.6° – 365° F.); composition $H_2C_{11}H_{10}O_7$. (*A. Pharm.*, Feb. 1901.)

The action of the drug upon the lower animals has been studied by J. Ott and A. C. Nagle with similar results. (*Jamaica Dogwood*, Parke, Davis & Co., 1881.) The conclusions reached are, 1. It is narcotic to frogs, rabbits, and men. 2. It does not affect the irritability of the motor nerves. 3. It does not attack the peripheral ends of the sensory nerves. 4. It reduces reflex action by a stimulant action on the centres of Setschenow. 5. It produces a tetanoid state by a stimulant action on the spinal cord, and not by a paralysis of Setschenow's centres. 6. It dilates the pupil, which dilatation passes into a state of contraction upon the supervention of asphyxia. 7. It is a salivator. 8. It increases the secretion of the skin. 9. It reduces the frequency of the pulse. 10. It increases arterial tension by stimulation of the vasomotor centre. 11. This increase of pressure is soon succeeded by a fall, due to a weakening of the heart itself.

The exact practical value of the drug has not been determined, nor are the results produced in man, by doses approaching toxic, known. Hamilton took a drachm, when suffering with severe toothache, on going to bed. He first felt a violent sensation of heat internally, which gradually extended to the surface, and was followed by profuse perspiration, with profound sleep for twelve hours. On awaking, he was quite free from pain, and without the unpleasant sensations which follow a dose of opium. Various practitioners have reported good results from its use as an anodyne in *neuralgia*, *nervous insomnia*, *whooping cough*, etc., but in other hands it has failed to do good. H. C. Wood found it in one case of neuralgia to produce great nausea and gastric distress without evincing the slightest narcotic effect. Joseph L. Lemberger offers a formula for the preparation of a *fluidextract*, as follows. Forty-eight troyounces of the bark, in No. 8 powder, are moistened with sufficient of a mixture of three pints of alcohol, half a pint of glycerin, and half a pint of water; it is packed in a percolator, allowed to stand for six hours, and then percolated with the menstruum until three pints of percolate are obtained. (*D. C.*, 1881, 179.) The dose of the fluidextract is a fluidrachm (3.75 Cc.), to be carefully increased.

Pithecolobium.—*Pithecolobium Saman*, Benth. (Fam. Leguminosæ).—A shade-tree, indigenous in South America and planted for shade in Japanese coffee plantations, which yields a poisonous alkaloid, *pithecolobine*, whose physiological action is analogous to that of sapotoxin.

Pixel is a form of wood tar, soluble in water, made by warming three parts of wood tar and one part of green soap together and gradually adding three parts of a 10 per cent. solution of potassium hydroxide with stirring. It is a clear dark brown syrupy liquid. The disinfecting power of a 5 per cent. solution is said to be not less than that of a 5 per cent. solution of phenol.

Plantago. *Plantago major*, L. *Plantain*. *Rib Grass*. *Ribwort*. *Ripple Grass*. *Plantain*, Fr. *Wegerich*, G. (Fam. Plantaginaceæ).—The leaves are saline, bitterish, and austere to the taste; the root is saline and sweetish. The common plantain weed was formerly considered refrigerant, diuretic, deobstruent, and somewhat astringent. The ancients esteemed it highly, but it is at present never used, except it be externally in domestic practice as a stimulant application to sores. The leaves are put on whole or bruised in the form of a poultice. *Plantago media*, L., and *P. lanceolata*, L., or *rib grass*, which are also naturalized in America, possess properties similar to those of *P. major*, and may be used for the same purposes.

Theo. Koller, in 1868, obtained from the leaves of *Plantago major*, *P. lanceolata*, and *P. media*, chlorophyll, resin, wax, albumen, pectin, citric acid, and oxalic acid. David Rosenbaum found in the leaves of *P. major*, wax, chlorophyll, resin, and a notable quantity of calcium oxalate. (*A. J. P.*, 1886, 418.) J. F. Strawinski found in the rhizome a substance which he believes to be either phlobaphene or protocathechuic acid. (*A. J. P.*, 1898, 189.)

Semen psyllii is the name given to the seeds of several species of European *Plantago*. The best are those of *Plantago Psyllium*, L., or *fleawort*, which grows in the south of Europe and in Barbary. They are small, about a line long by half a line in breadth, convex on one side, concave on the other, flea-colored, shining, inodorous, and nearly tasteless, but mucilaginous when chewed.

They are demulcent and emollient, and may be used internally and externally in the same manner as flaxseed, which they closely resemble in medicinal properties. *Spogel seed*, used in India as a demulcent in intestinal irritation, is derived from *P. Isphagula*, Roxb., probably a variety of *P. ovata*, Forsk. (See *Journ. Méd. de Paris*, Sept. 1887.)

Platinum. *Platine*, Orblanc, Fr. *Platin*, G. Colloidal platinum, formed by the action of an electric arc between platinum wires under water, forms in water a deep black liquid which has a strong catalytic effect, resembling in many respects the action of organic ferments. The most useful salt of platinum is the *tetrachloride*, $\text{PtCl}_4 \cdot 5\text{H}_2\text{O}$, which may be obtained by mixing an aqueous solution of chloroplatinic acid, H_2PtCl_6 , with a solution of silver nitrate; a precipitate containing the silver, combined with some platinum and chlorine, separates, and the yellowish-red solution yields on evaporation fine large red crystals of *platinum chloride*. The compound usually called platinum chloride is said by Roscoe and Schorlemmer to be *chloroplatinic acid*, $\text{H}_2\text{PtCl}_6 \cdot 6\text{H}_2\text{O}$, and is made by dissolving the metal in nitro-hydrochloric acid, and evaporating with hydrochloric acid until all the nitric acid is removed. In 1826 Gmelin of Tübingen, made experiments to determine the action of this metal on the economy. In 1841 Ferdinand Hofer published some observations on the same subject. The latter experimented chiefly with the chloride, formerly called *bichloride*, and the double *platinum and sodium chloride*. They are both poisonous, the chloride when given in the quantity of fifteen grains (1 Gm.), the double chloride in that of thirty grains (2 Gm.). When a concentrated solution of the chloride is applied to the skin, it produces violent itching, followed by an eruption; administered internally, it irritates the mucous membrane of the stomach and occasions headache. The double chloride has no action when externally applied, and, when given internally, operates on the system in a less sensible manner than the chloride. It possesses the power of augmenting the urine. Hofer ranks the preparations of platinum with the alteratives, by the side of those of iodine, arsenic, and gold. He considers them particularly suited to the treatment of *syphilitic diseases*: the chloride to cases of long standing and inveterate, the double chloride to those which are recent. Eight grains may be made into sixteen pills, with a drachm of the extract of guaiacum wood of the French Codex, and sufficient powdered licorice root. Of these, one, two, or three may be taken morning and evening. The double chloride may be prepared by dissolving five grains of the chloride and eight of pure sodium chloride in seven fluidounces of gum water, and the whole may be taken by tablespoonfuls in the course of twenty-four hours. For frictions on *indolent ulcers*, Hofer used an ointment composed of fifteen grains (1 Gm.) of the chloride, thirty grains (2 Gm.) of extract of belladonna, and an ounce (31 Gm.) of lard. (*J. P. C.*, xxvii. 213.) The dose of the chloride is from half a grain to two grains (0.032–0.13 Gm.) twice a day, given in pill.

Plumbago europæa. L. *Leadwort*. *Dentelaria*. (Fam. *Plumbaginaceæ*.)—A perennial, herbaceous plant, growing in the south of Europe. It has an acrid taste, and, when chewed, excites a flow of saliva. This is particularly the case with the root, which has been long used to relieve toothache; hence its French name *dentelaire*. A

decoction of the root in olive oil has been highly recommended for *itch*. A crystallizable, acrid principle, called *plumbagin*, has been extracted from the root by Dulong. (*J. P. C.* (2), xiv. 441.) *Plumbago zeylanica* is said to be a very powerful diaphoretic.

Pneumin.—This is a yellowish, odorless, tasteless powder obtained by the action of formaldehyde upon creosote, freely soluble in alcohol and ether; insoluble in water. It is supposed to be a mixture of the methylenic compounds of phenols of beech tar and their ethers, and has been recommended by Jacobson in the treatment of *tuberculosis* and in *pulmonic catarrh* in doses of eight grains (0.5 Gm.) three to five times a day, as required. (See *Med. Wochen.*, 1900, No. 36; 1901, No. 4.)

Polyformin.—Two kinds of polyformin are found in commerce, soluble and insoluble. The soluble form, *di-resorcin-hexa-methylene-tetramine*, $(\text{C}_6\text{H}_4(\text{OH})_2)_2 \cdot (\text{CH}_2)_6\text{N}_4$, occurs in handsome colorless crystals, soluble in water and alcohol, insoluble in ether and oils, and is used as an antiferment and diuretic. Insoluble polyformin results when polyatomic phenols or such as possess condensed benzene nuclei are dissolved in formaldehyde, an excess of ammonia being added subsequently; if resorcinol be used, the polyformin is odorless, amorphous, and yellowish brown in color. The name polyformin is applied particularly to that kind which is employed as a bactericide.

Polygala. *Polygala polygama*, Walt. (*P. rubella*, Muhl.) (Fam. *Polygalaceæ*.) *Bitter Milkwort*. *American Bitter Polygala*. *Polygale*, Laitier, Fr. *Kreutzblume*, *Milchwurz*, G.—*Bitter polygala* is an indigenous, perennial plant, which was formerly official. It has a strong and permanent bitter taste, which it yields to water and alcohol. In small doses bitter polygala is tonic, in larger, laxative and diaphoretic. It appears to be closely analogous in medicinal virtues to *Polygala amara*, L., of Europe, which is used for a similar purpose. From the seeds of the *P. butyracea*, Heck. and Schlag., an African plant, the natives prepare an edible fat. (See *P. J.*, xx. Aug. 1889.)

Polymnia. *Polymnia Uvedalia*, L. *Bear's Foot*. (Fam. *Compositæ*.)—Great virtues as a remedy in *malarial splenic enlargements* have been attributed to this North American plant. (See *Newer Mat. Med.*, 53.)

Polypodium.—Various species of this genus of ferns are asserted to have medicinal properties. *Polypodium vulgare*, L., very common both in Europe and America, was believed by the ancients to be an active cholagogue purgative, and has been used in modern times as an expectorant in chronic *catarrh* and *asthma*. *Dose*, from one to eight drachms (3.9–31 Gm.), usually given with a cathartic. The rhizome, as it usually occurs in commerce, is about as thick as a goose quill, somewhat contorted, covered with brown, easily separable scales (often wanting), furnished with slender radicles, and marked by numerous small tubercles. Its color is reddish brown with a tinge of yellow, its odor disagreeably oleaginous, its taste peculiar, sweetish, somewhat bitter, and nauseous. *P. adiantiforme*, of Porto Rico, is believed by the natives to be a powerful antisyphilitic. It must be used freely for several months in the advanced stages of the disease. *P. friedrichsthalianum*, of Central America, has similar properties attributed to it.

Polytrichum. *Polytrichum juniperinum*, Hedw. *Hair Cap Moss*. *Robin's Kye*.—This indigenous moss is stated by William Wood to be a powerful diuretic, and, when given indefinitely in infusion, very useful in *dropsy*. (*Am. J. M. S.*, N. S., xxvii, 267.) Ariel Hunter confirms these statements. (*N. J. Med. Rep.*, ix, 417.)

Pongamia. *Pongamia glabra*, Vent. (Fam. Leguminosæ.)—*Pongamia* or *kurung oil* is expressed from the seeds of an East Indian tree. It is deep yellow to reddish brown, fluid at 15.6° C. (60° F.), but below that it is solid with sp. gr. of 0.9352 (*P. J.*, 72, p. 492). It is especially commended in *pityriasis versicolor* and other parasitic skin diseases. (*P. J.*, February, 1883.)

Populus. *Poplar*.—In most trees belonging to this genus the leaf-buds are covered with a resinous exudation, which has a peculiar, agreeable, balsamic odor, and a bitterish, balsamic, somewhat pungent taste. It is abundant in the buds of *Populus nigra*, L., or the *black poplar* of Europe, which are official in some parts of that continent. They contain resin and a peculiar volatile oil. The buds of *P. balsamifera*, L., growing in the northern parts of North America and Siberia, are also highly balsamic; and a resin is said to be furnished by the tree, which is sometimes, though erroneously, called *tacamahac*. Balm of Gilead buds are obtained from *P. balsamifera* var. *candicans*. The virtues of the *poplar buds* are probably analogous to those of the turpentine and balsams. They have been used in pectoral, nephritic, and rheumatic complaints, in the form of a tincture, and a liniment, made by macerating them in oil, has been applied externally in local *rheumatism*. The *unguentum populeum* of European pharmacy is made, according to the directions of the French Codex, by bruising in a marble mortar, and boiling in 2000 parts of lard, with a gentle fire, till the moisture is dissipated, 250 parts, each, of the fresh leaves of the white poppy, deadly nightshade, henbane, and black nightshade; then adding of the dried buds of the black poplar, bruised, 400 parts; digesting for twenty-four hours; straining with strong expression, and finally allowing the ointment to cool after defecation. This is an anodyne ointment, occasionally employed in Europe in painful local affections. It has been ascertained that poplar buds are capable of imparting a principle to ointments which obviates their tendency to rancidity.

The bark of *P. tremuloides*, Michx., or *American aspen*, and of *P. tremula*, L., or *European aspen*, is possessed of tonic properties, and has been used in *intermittent fever*. In the bark of the latter Braconnot found *salicin*, $C_{13}H_{15}O_7$, and another crystallizable principle which he named *populin*, $C_{20}H_{22}O_8$. It is in these, probably, that the febrifuge properties of the bark reside. They may be obtained by precipitating a saturated decoction of the bark with solution of lead subacetate, filtering, precipitating the excess of lead by sulphuric acid, again filtering, evaporating, adding animal charcoal towards the end of the evaporation, and filtering the liquor while hot. Salicin gradually separates, upon the cooling of the liquor, in the form of crystals. If, when this principle has ceased to crystallize, the excess of sulphuric acid in the liquid be saturated by a concentrated solution of potassium carbonate, the populin will be precipitated. If this be pressed between folds of blotting paper, and redissolved in boiling water, it will be deposited, upon the

cooling of the liquid, in the crystalline state. The leaves of *P. tremula* are also said to yield more populin than does the bark. It is probable that both principles exist in the bark of *P. tremuloides* and other species. Schaak (*A. J. P.*, 1892, 226) found a bitter principle in the bark of *P. alba*, L., which was most likely populin. Salicin is described under *Salix*. *Populin* is very light, purely white, of a bitter, sweetish taste, analogous to that of licorice. It is soluble in 1896 parts of cold and about 70 parts of boiling water, and is more soluble in boiling alcohol. It loses its two molecules of water of crystallization at 100° C. (212° F.), and at 180° C. (356° F.) it fuses to a colorless liquid, from which at a higher temperature benzoic acid may be sublimed. Acetic acid and the diluted mineral acids dissolve it, and, upon the addition of an alkali, let it fall unchanged. Piria first showed it to be *benzoyl salicin*, $C_{13}H_{17}(C_7H_5O)_7 + 2H_2O$. He then decomposed it and prepared salicin from it. Populin has been prepared synthetically by Schiff and by Dobbin and White (*P. J.*, 73, p. 233). When populin is boiled with baryta water or milk of lime, the benzoic acid precipitated by ferric chloride, the excess of iron removed by lime, and the excess of lime by carbon dioxide, the remaining liquid yields salicin on evaporation. The same conversion may be effected by heating populin with an alcoholic solution of ammonia to 100° C. (212° F.). Piria obtained from populin 28.9 per cent. of benzoic acid. (*P. J.*, xv, 378.) T. L. Phipson, basing his experiments upon the results of Piria, has succeeded in preparing populin artificially by combining salicin and benzoic acid. Nothing more is necessary than to dissolve the two substances in alcohol, and to concentrate the solution. Crystals are formed having all the characters of populin, and consisting of salicin and benzoic acid combined in the proportion of their equivalents. (*Chem. News*, Dec. 6, 1862, 278.) The flower-buds of *P. tremuloides* yielded a bitter resin to R. Glenk. It was of yellowish-brown color, strong hop-like odor, and had a melting point of 51° C. (123.8° F.). (*A. J. P.*, 1889, 240.)

Portulaca. *Portulaca oleracea*, L. *Garden Purslane*. (Fam. Portulacaceæ.)—This indigenous annual has been considered a cooling diuretic, and recommended in *scurvy* and urinary affections. The seeds have been thought anthelmintic, but are inert.

Potassio-Mercuric Iodide. *Mercuric Potassium Iodide*. *Iodohydrargyrate of Potassium*.—It has been found by chemists that mercuric iodide, HgI_2 , unites with the more positive metallic iodides, forming a series of double salts, sometimes called *iодоhydrargyrate*s. These have been particularly studied by Boullay (*Ann. Ch. Phys.* [2], 34, 345), who finds that a concentrated solution of potassium iodide will dissolve mercuric iodide in the ratio of three molecules of the mercuric salt for every two of the potassium salt. When the solution is cooled, one molecule of red mercuric iodide crystallizes out, and then from the mother liquor deposits yellow prisms, having the composition $2(HgI_2.KI) + 3H_2O$. Clayton suggests the practical method of simply evaporating Nessler's reagent and collecting the crystals. (*Chem. News*, 1894, 102.) This is an active preparation, which may be given in the same dose and for the same purposes as corrosive sublimate. It is formed when its components are prescribed together extemporaneously. It is not decomposed by the compound syrup of sarsaparilla, which is frequently used as a vehicle for it.

Potassio-mercuric iodide was suggested by F. L. Winckler as a qualitative test of the organic alkaloids. F. F. Mayer subsequently employed, for volumetric analysis, a solution made with 13.546 grammes of corrosive sublimate, 49.8 grammes of potassium iodide, and a liter of distilled water. (See *Mercurio Potassium Iodide Test Solution*, U. S. D., PART III.) For further observations, see A. J. P., 1886, 579, and 1887, 1.

Potassium Bisulphate. *Potassii Bisulphas.* Acid Sulphate of Potassium. $\text{KHSO}_4 = 135.21$. "Take of Potassium Sulphate, in powder, three ounces [avoirdupois]; Pure Sulphuric Acid one fluid ounce [Imperial measure]. Place the Acid and Salt in a small porcelain capsule, and to this apply a heat capable of liquefying its contents, and which should be continued until acid vapors cease to be given off. The Bisulphate, which concretes as it cools, should be reduced to a fine powder, and preserved in a well-stopped bottle." Br. It is often a by-product in chemical operations, being left as residue when potassium salts are decomposed by sulphuric acid in excess. It is a white salt, the crystals having the form of right rhombic prisms so flattened as to be tabular. The salt has a bitter and extremely acid taste. It is soluble in twice its weight of cold and in less than its weight of boiling water. Alcohol does not dissolve it, but when added to an aqueous solution, precipitates the neutral sulphate. Exposed to the air, it effloresces slightly on the surface, and when moderately heated readily melts, and runs like oil. At a red heat it loses water and the excess of acid, and is reduced to a neutral sulphate. Owing to its excess of acid, it acts precisely as an acid on the carbonates, causing them to effervesce. It is incompatible with alkalies, alkaline earths, and their carbonates, with many of the metals, and with most oxides. This salt was formerly called *sal enixum*. It is aperient. It answers, according to Barker, for preparing a cheap aperient effervescing draught. Equal weights—a drachm, for instance—of the bisulphate and of sodium carbonate may be dissolved separately, each in two fluidounces of water, then mixed, and taken in the state of effervescence. Dose, one or two drachms (3.9–7.7 Gm.).

Potassium Bromate. *Potassii Bromas.* Bromate de potasse, Fr. *Kaliumbromat*, *Bromsaures Kali*, G. KBrO_3 .—This salt is formed in the process employed for making the bromide and may be separated by crystallization. Colorless, cubical or tabular crystals, soluble in 15 parts of cold and 2 parts of hot water. Like potassium chlorate it oxidizes matter like sugar and sulphur and must be mixed with great caution, with readily oxidizable substances. It is an ingredient in *Koppeschaar's solution* (which see) and is employed in titrating phenol.

Potassium Chloride. *Potassii Chloridum.* *Kalium chloridum* (chloratum). *Sal digestirum Sylvii*. *Sel digestif*, Fr. KCl .—An important source of this salt is *carminite*, a double chloride of potassium and magnesium mined at Stassfurt. In colorless, cubical prisms, without odor, the taste resembling common table salt; very soluble in water, slightly so in alcohol. It is chiefly of value as the source of other potassium compounds.

Potassium Chloro-Platinite.—Eight grains (0.5 Gm.) of this salt, which is used as a toning agent in photography, caused death in an infant of two months, preceded by violent gastro-enteritis and collapse. (B. M. J., i. 1896.)

Potassium Cobalti-Nitrite. $\text{Co}_2(\text{NO}_2)_2 \cdot 12\text{K}_2\text{O} + 2\text{H}_2\text{O} = 934.32$.—When potassium nitrite is added to a cobalt salt solution acidified with acetic acid, nitrogen is set free, and in course of time the double cobaltic and potassium nitrite separates as a yellowish crystalline powder, almost totally insoluble in acid solution. Wolcott Gibbs having suggested that this nitrite might be less fugacious than other nitrites, on account of its stability and relative insolubility, J. W. Roosevelt tried it in doses of from one-quarter to one-half grain (0.016–0.032 Gm.), every two hours, in kidney cases with high arterial tension and dyspnea, in *asthma*, and also in *cardiac valvular diseases*. He stated that the effects of the drug are similar to those of the nitrites, beginning in fifteen minutes and lasting from two to four hours.

Potassium Ferricyanide. *Ferridcyanide of Potassium.* *Red Potassium Prussiate.* $\text{K}_3\text{Fe}(\text{CN})_6$. This is formed by passing a current of chlorine through a solution of potassium ferrocyanide, until the liquid ceases to form a precipitate with a solution of ferric chloride, a proof that the whole of the ferrocyanide has been converted into the ferricyanide. The solution, by due evaporation, yields the compound in question. It may also be prepared, in the dry way, by agitating finely powdered ferrocyanide with chlorine as long as it is absorbed. The theory of the formation of this compound is that two atoms of chlorine withdraw from two molecules of the ferrocyanide two atoms of potassium, forming potassium chloride, which remains in the mother water, while the two atoms of iron, having assumed the ferric condition, together with the remaining potassium, saturate the cyanogen. The reaction is explained by the following equation:

The radical ferricyanogen is supposed to be formed by the coalescence of two molecules of ferrocyanogen, and is sometimes represented by the symbol *Cfdy*. This salt, discovered by Gmelin, is in beautiful deep hyacinth-red anhydrous crystals, which are soluble in four parts of water. Its solution forms a delicate test for ferrous salts, with which it produces a blue precipitate; but with ferric salts it only strikes a green or brown color. It is used in dyeing and calico printing. (See *Test Solutions*, PART III.)

Potassium Glycerophosphate. *Potassii Glycerophosphas.* $\text{C}_3\text{H}_7\text{O}_5\text{PO}_3\text{K}_2$.—The salt is very hygroscopic and has an alkaline reaction. A more permanent commercial form is a 50 per cent. aqueous solution. It is used as a tonic and nerve in doses of from three to six grains (0.2–0.4 Gm.).

Potassium Iodate. *Potassii Iodas.* *Iodate de Potasse*, Fr. *Kaliumjodat*, *Jodsaures Kali*, G. Demarquay and Custin propose the following mode of preparation, which is followed by the Br. Pharm. (1885) in making its test solution. Take of iodine and potassium chlorate, each, one part, and mix them with five or six parts of water, previously acidulated with a few drops of nitric acid, and heated to ebullition. As soon as chlorine ceases to escape, treat the liquid with a concentrated solution of barium chloride. Wash with distilled water, and decompose with diluted sulphuric acid the barium iodate precipitated; filter to separate the barium sulphate, and slowly evaporate the solution. Wash with distilled water the crystals of iodic acid that are formed, dissolve them in boiling distilled water, and saturate with potassium bicarbonate. On cooling the iodate is

deposited in small crystals. Stas prepares it by moderately heating equal molecular weights of potassium iodide and chlorate, dissolving out the chloride formed with cold water, and repeatedly crystallizing the iodate from hot water. (*A. J. P.*, 1870, 217.) Egidio Pollacci has found that phosphorus affords a very delicate test for the iodate, as does also the iodate for phosphorus, free iodine being liberated. (*J. P. O.*, 4e sér., xx, 104.) Demarquay and Custin assert that potassium iodate is superior to potassium chlorate as a local remedy in ulcerative and gangrenous stomatitis, pyralism, diphtheria, and other diseases of the pharyngeal and buccal mucous membrane. Dose, from four to eight grains (0.26–0.5 Gm.). (*Dorvault's Rev. Pharm.*, 1858.)

Potassium Nitrite. *Potassii Nitris.*—Nitrite of Potassium ($\text{KNO}_2 = 84.55$) is most readily obtained by fusing saltpetre with lead, which withdraws one atom of oxygen from the former, changing it thereby to litharge. It is a white, fusible, and uncrystallizable mass, usually cast into sticks like the hydroxide. It is very deliquescent, and absorbs carbon dioxide from the air. It shares the activities of the nitrites, producing in animals their physiological effects, and being capable of replacing them in the treatment of disease. Its influence is comparatively slow and permanent. Five grains (0.32 Gm.) have produced mild poisoning. Dose, three grains (0.2 Gm.).

Potassium Percarbonate, $\text{K}_2\text{C}_2\text{O}_6$, is a colorless powder which slowly decomposes under the action of water, as follows:

In the presence of sulphuric acid, potassium percarbonate decomposes and forms hydrogen peroxide.

$\text{K}_2\text{C}_2\text{O}_6 + 2\text{H}_2\text{SO}_4 = 2\text{KHSO}_4 + 2\text{CO}_2 + \text{H}_2\text{O}_2$
This substance has not as yet been used in practical medicine, but is believed to be the material known as *anthypo*, much used in photography, and which has been recommended by Müller for the purposes of decolorizing and counterstaining tubercular bacilli. He washes the preparations for this purpose in 50 to 70 per cent. alcohol and places them for fifteen minutes in a 5 to 10 per cent. solution of potassium percarbonate, and after differentiating rinses in water and counterstains with methylene blue.

Potassium Perchlorate. *Potassii Perchloras.* *Hyperchlorate of Potassium.* $\text{KClO}_4 = 137.56$. This salt is prepared by fusing potassium chlorate until it begins to assume a pasty condition. The cooled mass consists of potassium perchlorate and chloride. The absence of undecomposed chlorate may be known by a sample failing to communicate a yellow color to hydrochloric acid. The mass must be dissolved in the smallest possible quantity of boiling water, when perchlorate crystallizes out. It is sparingly soluble in water, and insoluble in alcohol. Its effects are wholly different from those of potassium chlorate, and it has been commended in intermittents. (*Ann. Thér.*, 1869, 141.)

Potassium Persulphate. *Potassii Persulphas.* *Kaliumpersulfat*, G. *Anthion*.—Obtained by electrolyzing a solution of potassium bisulphate. Colorless crystals, soluble in about 50 parts of water. Used in photography, owing to its oxidizing of sodium thiosulphate to sulphate.

Potassium Phosphate. *Potassii Phosphas.* *Phosphate of Potassium.* $\text{K}_2\text{HPO}_4 = 173.01$.—The potassium phosphate which has come into use as a medicine is the *dipotassic orthophosphate*, having a composition precisely analogous to that of the medicinal sodium and ammonium phosphates. It

may be formed precisely as sodium phosphate is prepared; or by nearly saturating, by means of potassium carbonate, common or orthophosphoric acid, H_3PO_4 . The medicinal potassium phosphate is a white, amorphous, deliquescent salt, crystallizing with difficulty. It has been given as an alternative in *scrofula* and *phthisis* with supposed advantage. The dose is from ten to thirty grains (0.65–2.0 Gm.), three times a day, dissolved in a teaspoonful of water.

Potassium Picrate. *Potassii Picras.* *Kalium-pikrat*, *Pikrinsaures Kalium*, G. $\text{C}_6\text{H}_3(\text{NO}_2)_3\text{OK}$. This salt may be made by neutralizing a hot solution of 20 parts of picric acid with 7 parts of potassium carbonate and crystallizing in a cool place. Small yellow crystals, or a yellow powder of a bitter taste, soluble in 230 parts of cold water and 15 parts of hot water; nearly insoluble in alcohol. It must be handled with care as it explodes by a blow or when heated.

Potassium Silicate. *Potassii Silicas.*—*Silicate of Potassium*, K_2SiO_3 , also known as *soluble glass*, is prepared in the same way as the sodium salt. These salts have been used in *rheumatism*, *gout*, etc. (*A. J. P.*, 1857, 314; *Ann. Thér.*, 1865, 236), but are probably of no service. They form excellent substitutes for starch, dextrin, and plaster of Paris in the preparation of immovable surgical dressings. The solution is applied, of a syrupy consistence, by means of a brush, to the bandages, upon which it rapidly hardens, requiring only five or six hours for this result. The facility of removing the bandages by means of hot water is another advantage which potassium silicate possesses over most other dressings. (*J. P. O.*, 4e sér., iv.)

Potassium Sulphite. U. S. 1880. *Potassii Sulphis.* $\text{K}_2\text{SO}_3 \cdot 2\text{H}_2\text{O} = 192.95$. *Kali Sulfurosum*, *Sulfis Potassious*, S. *Kalicus. Sulfite de Potasse*, Fr. *Schweefigsaures Kali*, G.—Potassium sulphite is prepared by causing sulphurous acid to pass through a strong solution of potassium carbonate until decidedly acid; an equal weight of potassium carbonate is now added. The sulphite crystallizes out upon standing. "White, opaque, obliquely-rhombic, octahedral crystals, or a crystalline powder, somewhat deliquescent, odorless, having a bitter, saline, and sulphurous taste, and a neutral or feebly alkaline reaction. Soluble in 4 parts of water at 15° C. (59° F.) and in 5 parts of boiling water; only sparingly soluble in alcohol. When gently heated, the salt loses its water of crystallization (18.5 per cent.); at a red heat it is decomposed and leaves a residue of an alkaline reaction. The aqueous solution of the salt yields a white, crystalline precipitate on the addition of a saturated solution of bitartrate of sodium. Addition of diluted hydrochloric acid to the aqueous solution gives rise to the odor of burning sulphur, and the solution does not become cloudy (difference from *hyposulphite*)."
U. S. 1880. It decrepitates when heated. In the air it effloresces, absorbing oxygen, and being partially converted into the sulphate. The occurrence of a yellow precipitate, when it is added to a solution of platonic chloride, shows that it is a salt of potassium. "A one per cent. aqueous solution of the salt, strongly acidulated with hydrochloric acid, should produce no precipitate, or, at most, only a white cloudiness, on the addition of a few drops of test-solution of chloride of barium (limit of sulphate). If 0.485 Gm. of the salt be dissolved in 25 Cc. of water, and a little gelatinized starch added, at least 45 Cc. of the volumetric solution

of iodine should be required, until a permanent blue tint appears after stirring (corresponding to at least 90 per cent. of pure Potassium Sulphite)." *U. S.* 1880.

The medicinal uses of this salt are essentially those of the other sulphites. It acts only as a slight laxative and diuretic. From four to six drachms (15.5–23.5 Gm.) in twenty-four hours have been given without unpleasant results. It escapes from the system with the urine, and may be found for some hours unchanged in the state of the sulphite; at the end of twenty-four hours potassium sulphate is found in the urine instead of the sulphite, proving that the salt undergoes oxidation in the body. It was at one time much used as a germicide in bacterial diseases, but has no power over microscopic organisms in the blood, and has passed out of vogue.

The local effects of the salt are probably less doubtful than the constitutional, but even as a local remedy it is inferior to sodium sulphite and sulphurous acid. *Dose*, from fifteen grains to a drachm (1–3.9 Gm.), repeated so as to amount to from a fourth of an ounce to an ounce in twenty-four hours.

Potassium Sulphocyanate. *Potassii Sulphocyanas*. *KSCN*. *Sulphocyanure de Potassium*, *Fr.* *Kalium Sulfoeyanat*, *Rhodankalium*, *G.*—Potassium sulphocyanate, formerly called potassium sulphocyanide, is prepared by fusing in an iron vessel, at a low red heat, a mixture of two parts of dried potassium ferrocyanide and one part of sublimed sulphur. The mass, when cold, is dissolved in boiling water, and to decompose some ferric sulphocyanate, the solution is treated with potassium carbonate, which throws down the iron as a carbonate, and gives rise to the formation of a fresh portion of potassium sulphocyanate. The whole is then boiled for a quarter of an hour, filtered to separate the precipitated iron, and evaporated that crystals may form. These are purified from potassium carbonate by being dissolved in alcohol, which takes up the sulphocyanate and leaves the carbonate. The alcoholic solution is then allowed to crystallize. Potassium sulphocyanate is in long, striated, anhydrous prisms, deliquescent in a moist atmosphere, very soluble in alcohol, and having a cooling, somewhat biting taste. It has been proposed by Sömmerring as a substitute for hydrocyanic acid and potassium cyanide, on the ground that it possesses the same therapeutic properties without their inconveniences.

Potentilla.—*Potentilla reptans*, *L.*, the creeping cinquefoil of Europe, and *Potentilla canadensis*, *L.*, the common cinquefoil of America (Fam. *Rosaceæ*), have each been used as astringents in *diarrhœa*, *chronic catarrhs*, *night sweats*, etc. According to *J. C. Peacock* (*A. J. P.*, 433, 1900), dried *P. norvegica*, *L.*, contains four, and *P. canadensis* thirteen, per cent. of tannic acid.

Powder of Algaroth. *Pulvis Algarothi*. *Oxychloride of Antimony*. *Nitro-muriatic Oxide of Antimony*.—A powder rarely used now. For a description of its uses, properties, etc., see 14th edition *U. S. D.*

Prasoid.—A solution, of which one hundred drops contain 0.135 Gm. of *globularin* and 0.153 Gm. of *globularetin*. It is used in *gout* and *rheumatism* in doses of from fifteen to twenty drops (0.75–1.0 Cc.), three times daily.

Primula.—The leaves of the various species of this genus produce irritation when handled, due to a secretion in the glandular hairs. From the roots of *Primula grandiflora*, *Bongault* and *Alland*

have separated a crystalline polyatomic alcohol, *primulite*, which is said to be identical with the heptatomic alcohol *volemite*. (*C. R. A. S.*, 135, 796.)

Prinos. *Black Alder*. *Winterberry*. *Feverbush*. *Prinos*, *Fr.*, *G.*—The *U. S. P.* formerly recognized under this name the bark of *Ilex verticillata* (*L.*), *A. Gray* (*Prinos verticillatus*, *L.*) (Fam. *Ilicaceæ*). This shrub grows in the United States from Canada to Florida; and west to Missouri and Wisconsin, frequenting low, wet places. The berries, which have a bitter, sweetish, somewhat acrid taste, are sometimes used medicinally for the same purposes as the bark. The dried bark was officially described as in "thin, slender fragments, about one-twenty-fifth of an inch (1 Mm.) thick, fragile, outer surface brownish ash-colored, with whitish patches and blackish dots and lines, the corky layer easily separating from the green tissue; inner surface pale greenish or yellowish; fracture short, tangentially striate; nearly inodorous, bitter, slightly astringent." *U. S.* 1880. It has no odor, but a bitter and slightly astringent taste. Boiling water extracts its virtues. *William J. Lerch* failed to find berberine in it. (*A. J. P.*, 1873, 251.)

Black alder has been considered tonic and astringent, and has been used in *diarrhœa* and as a substitute for Peruvian bark, but has no antiperiodic properties. In cases of flabby or ill-conditioned ulcers it is popularly used both locally and internally in decoction (two ounces in three pints of water boiled to a quart). *Dose*, from two to three fluidounces (60–90 Cc.).

Prioria. *Prioria Copaifera*. *Griseb.* (Fam. *Leguminosæ*).—The oil tree is a native of the West Indies, where it attains the height of eighty feet, and yields an exudate which is known as the gum of the oil tree. This is a thick adhesive liquid, resembling copaiba, usually turbid on account of a greenish substance, which, however, finally subsides, leaving a clear, brownish-yellow liquid. For chemical study, see *A. J. P.*, Jan. 1898.

Propione. *Di-ethyl-ketone*. $C_2H_5.CO.C_2H_5$. (Corresponding to acetone or di-methyl-ketone.) A mobile, easily soluble liquid, boiling at 101° C. (213.8° F.). *Dose*, as an hypnotic, from eight to forty-five grains (0.5–3.0 Gm.).

Propyl Alcohol (normal propyl alcohol, $C_2H_5.CH_2OH$) is formed in the fermentation of certain sugar and wine residues, as from the marc of grapes, and is separated from the fusel oil of this fermentation. It is a colorless, pleasant-smelling liquid, boiling at 96° C. (204.8° F.).

Protargol. *Protargolum*.—A combination of silver and albumin, containing about 8 per cent. of metallic silver. A yellow powder, soluble in 1 part of water, the solution not being affected by heat, albumin, hydrochloric acid, weak sodium chloride solution or sodium hydroxide solution. The dry salt as well as the solution should be protected from light. It is especially valuable because of its non-irritant properties; a 5 per cent. solution producing no pain, only a slight burning sensation, when applied to the eye. A ¼ to 2 per cent. solution may be used in acute gonorrhœa; a 5 to 10 per cent. solution in urethritis.

Protea. *Protea mellifera*, *Thunb.* (Fam. *Proteaceæ*). *Sugar Bush*.—A plant growing in South Africa, from the leaves of which *Merring Beck* in 1886 obtained *proteacin*. *Merck* and *Hesse* subsequently named the principle *leucodrin*. *Hesse*

found the leaves to yield from 2 to 5 per cent. of hydroquinone associated with proteacic acid. (*P. J.*, 1896, 426.)

Protozen.—An albuminoid compound, obtained by the action of formaldehyde on serum or egg albumin. Used as a dietetic food for children. Dose, two ounces (62 Gm.), twice daily in enema.

Prunella. *Prunella vulgaris*, L. *Self-heal*. *Heal-all*. *Brunella vulgaris*. *Paquerette*, Fr. *Braunelle*, *Braunheil*, G.—A small perennial labiate herb, which is common both in Europe and the United States. It was formerly used in hemorrhages and diarrhœa, and as a gargle in sore throat.

Psidium. *Psidium Guajava*, L. (*P. pomiferum*, L., and *P. pyrifera*, L.) (Fam. Myrtacæ.) *Guava*.—Hartwich has examined the root, bark, and leaves of this plant from India. (See *Ph. Rev.*, 1896, 257.)

Psoralea.—Of this genus (Fam. Leguminosæ) various species are useful. *P. castorea*, S. Wats., *P. mephitica*, S. Wats., and especially *P. esculenta*, Pursh, are all employed by the Indians of the Northwestern United States, and by the settlers, as articles of food, *P. esculenta* being the prairie turnip or prairie potato, the *tipsinah* and *taahgu* of the Indians. C. Richardson found in it nearly 70 per cent. of starch, and 5 per cent. of a new, rapidly crystallizing sugar, which has not been further investigated. *P. glandulosa*, L., *culen*, *yolochiahuitl*, of the Mexican Pharmacopœia, yields a leaf which is used as a tonic or anthelmintic, and an emetic root. *P. bituminosa*, of Europe, and *P. physodes*, Dougl., of California, are popularly considered tonic and emmenagogue, while *P. pedunculata* (Mill.), Vail. (*P. melilotoides*, Michx.) (Congo root, Bob's root, Samson's snake-root), of Virginia, has been recommended as an aromatic bitter tonic, especially useful in chronic diarrhœa. The part employed is the root, from which MacNair obtained about 2 per cent. of a volatile oil, having the specific gravity 0.93, a pungent and bitter taste, and a neutral reaction; also a bitter principle, but not tannin. For further description, see *A. J. P.*, July, 1889; also 14th and 16th editions of *U. S. D.* *P. corylifolia*, L., of India, yields an oleoresin which is used in the treatment of leucoderma and other skin diseases. (*P. J.*, Sept. 1881.)

Ptelea. *Ptelea trifoliata*, L. *Water Ash*. *Wing Seed*. *Shrubby Trefoil*. *Hop Tree*. *Orme à trois feuilles*, Fr. *Hopfenbaum*, *Kleebaum*, G. (Fam. Rutacæ).—This is a shrub, six or eight feet in height, growing in rocky places from Long Island to Florida and west to Texas and Minnesota. The root bark, dried, occurs in cylindrical rolls or quills, one or two lines in diameter and from one to several inches long, of a light brownish color, irregularly wrinkled, and covered with a thin epidermis. Internally it is a yellowish white, but darkens by exposure. It has a peculiar somewhat aromatic odor, and a bitter, persistently pungent, and slightly acrid, yet not disagreeable taste. It yields its virtue to water, but more readily to alcohol. Steer found it to contain an oleoresin of an acrid and bitter taste. He also extracted from it the alkaloid *berberine*, which is probably the tonic principle, while the oleoresin may impart to the bark somewhat stimulant properties. (*A. J. P.*, 1867, 337. See also *Ibid.*, 1862, 198.) It is said to have been much employed among the physicians of the Western States in the treatment of *dyspepsia*, and generally in diseases requiring a mild, non-irritating, bitter tonic.

Ptomaines.—Within recent years a class of very interesting compounds have been described and are known under this name. They are alkaloid-like bases obtained from animal tissue after decomposition has commenced, hence sometimes called *cadaveric alkaloids*. Bence Jones and Dupré (*Ph. Centralh.*, 16, No. 10) first published a notice of the finding of an alkaloid-like base from a decomposing human liver. Its sulphate solution fluoresced, and in other ways resembled quinine, yielding precipitates also with the usual alkaloidal reagents, potassio-mercuric iodide, phosphomolybdic acid, and gold and platinum chlorides. It appears, however, that Marquardt had isolated such bases even previous to this. The chief investigators of this class of alkaloids have been Selmi, who first systematically studied them and gave them the name ptomaines, and Brieger, who since 1882 has published a series of elaborate studies and has classified their reactions. From cadavers which had been buried one, three, six, and ten months, in different cases, Selmi obtained bases of strongly alkaline reaction, all of which formed characteristic crystalline compounds with a solution of hydrogen iodide containing dissolved iodine. Three were soluble in ether, but not poisonous; one, insoluble in ether but soluble in amyl alcohol, was in the highest degree poisonous, producing in rabbits tetanus, strong dilatation of the pupil, paralysis of the heart, and death. All of these bodies are precipitated by the usual alkaloidal reagents, although they do not give the color reactions of the alkaloids. They, however, change rapidly when exposed to the air. Brieger's researches established the additional fact that ptomaines are formed during the earlier stages of decay, and that they are in general of a non-benzenoid character, but that as putrefaction continues they gradually disappear and give place to well-known benzenoid compounds, phenol, cresol, indol, etc. Brieger studied the ptomaines from (a) putrid horse flesh, beef, and human muscular tissue; (b) from putrid fish; (c) from putrid cheese; (d) from putrid glue; and (e) from putrid yeast. The bases obtained are of two classes. At first are obtained oxygenated bases, like *choline*, $C_5H_{15}NO_3$, *muscarine*, $C_5H_{15}NO_3$, *neurine*, $C_5H_{13}NO$, *gadinine*, $C_7H_{15}NO_3$, and *tetanine*, $C_{13}H_{20}N_2O_4$. These seem later to disappear, and amines seem to be almost the only products. Among those mentioned, the simplest are *dimethylamine*, $(CH_3)_2NH$, *trimethylamine*, $(CH_3)_3N$, and *triethylamine*, $(C_2H_5)_3N$. A number of the others seem to be diamines, like *putrescine*, $C_4H_{12}N_2$, *cadaverine*, $C_5H_{14}N_2$, *saprine*, $C_5H_{15}N_2$, *neuridine*, $C_6H_{14}N_2$, all four discovered by Brieger in the cadaver, *collidine*, $C_8H_{11}N$, *hydrocollidine*, $C_{11}H_{13}N$, *parvoline*, $C_9H_{13}N$, and *tyrotosicon* (*di-azobenzene*), $C_8H_5N_2$, discovered by Vaughan in poisonous cheese and in ice cream which had been allowed to become stale.

The formation of these volatile and frequently actively poisonous bases in the cadaver would seem to make the task of the toxicologist very difficult when the search for poisonous bases has been delayed until decomposition has set in. Any reagent or reagents, therefore, which will enable the chemist to decide between vegetable bases and these ptomaines becomes very important. Brouardel and Bontury (*C. R. A. S.*, 92, 1056) state that they have found such a decisive reagent in potassium ferricyanide. This compound when treated with a solution of a pure vegetable alkaloid is unacted upon by it; while, under the same con-

ditions, it is instantly reduced to the state of ferrocyanide by a ptomaine, and thus becomes capable of forming Prussian blue with a ferric salt. Up to the present but two exceptions to this rule have been found,—morphine, which readily reduces potassium ferri-cyanide, and veratrine, which gives traces of such reduction. It is possible, however, that in this last case the reducing action is due to certain impurities which the investigators were unable to remove completely from the veratrine employed by them.

Ptomaines are probably devoid of medicinal properties, but are of great interest to the toxicologist, not only from a chemical standpoint, but also from the fact that they are excessively fatal in their effects upon the animal economy. The well-known action of putrescent flesh, the curious poisonings sometimes produced by lobsters and other animals which feed upon carrion, are in all probability caused by them. In regard to treatment of poisoning by putrid animal matters, our present knowledge only justifies the immediate evacuation of the stomach and bowels and the meeting of the various indications as they arise. For fuller information as to the formation of ptomaines, their detection, separation, and clinical features, see *Ptomaines and other Animal Alkaloids*, by A. C. Farquharson, M.D. Bristol, Eng.: John Wright & Co., 1892.

Pulmoform. Methylene-diguaiaicol.

$\text{CH}_2 < \begin{matrix} \text{C}_6\text{H}_5(\text{OCH}_3)(\text{OH}) \\ \text{C}_6\text{H}_5(\text{OCH}_3)(\text{OH}) \end{matrix}$. This is a substance obtained by the action of formaldehyde upon guaiacol. It is a yellow, tasteless powder, having the same properties as *pneumin*, for which it may be substituted in the same dose.

Pulmonaria. *Pulmonaria officinalis*, L. *Lungwort*. *Pulmonaire*, Fr. *Lungenkraut*, G. (Fam. Boraginaceæ).—An herbaceous perennial, European plant, sometimes cultivated. The leaves have been employed in *catarrh*, *hæmoptysis*, and *consumption*, but their virtues are doubtful.

Pulsatilla. U. S. 1890. *Pulsatilla*.—"The herb of *Anemone Pulsatilla* and of *Anemone pratensis* Linné (nat. ord. *Ranunculaceæ*), collected soon after flowering. It should be carefully preserved, and not be kept longer than one year." U. S. 1890.

The genus *Anemone* is composed of small herbal plants growing in almost all the temperate countries of the world, and probably possessed very generally of the acrid rubefacient properties of the *Ranunculaceæ*. The *A. ludoviciana*, Nutt. (*Pulsatilla ludoviciana* (Nutt.), Heller, *A. nuttalliana*, Gray), an American species, growing in Minnesota and other parts beyond the Mississippi, has been employed with supposed advantage by W. H. Miller of St. Paul, in chronic diseases of the eyes, in cutaneous eruptions, and in syphilitic affections. A. W. Miller also found *anemonin* in it. (*A. J. P.*, 1862, p. 300; see also *A. J. P.*, xlv. 299.) *A. nemorosa*, L., which is common in Europe, is said to act as a poison to cattle, producing bloody urine and convulsions. It is stated also to have proved, when applied to the head, a speedy cure for *tinea capitis*. It is probable that the American *A. quinquefolia*, L., at first described as a variety of *A. nemorosa*, has similar properties.

A. patens, L., var. *nuttalliana*, Gray, was formerly recognized as a source of *pulsatilla*. The plant is that mentioned in the foregoing paragraph as *A. ludoviciana*. As Gray has pointed out, it is more like *A. Pulsatilla*, L., than like *A. patens*, L.

A. Pulsatilla, L. (*Pulsatilla vulgaris*, Mill.) This plant has its flower-stalk from five to eight inches high, with large solitary flowers, having six dull violet-purple sepals, which are very downy on the exterior, and an involucre which is at first near the flower and afterwards becomes more remote. The radical leaves are on long footstalks, and two or three times divided into long linear segments. It is a very common plant in England and Northern Europe.

Beckurts obtained *anemone camphor* by treating in each case the aqueous distillate of *A. nemorosa*, *A. pratensis*, and *A. Pulsatilla* with chloroform. It is unstable, splitting easily into anemonin and anemonic acid, the latter, when treated with alkalis, yielding *anemoninic acid*, $\text{C}_{10}\text{H}_{12}\text{O}_6$. (*P. J.*, 1885, 365.) The formula of anemonin is $\text{C}_{10}\text{H}_8\text{O}_4$. It is only slightly soluble in cold alcohol, but readily soluble in hot alcohol, and very slightly soluble in boiling ether or water. It is decomposed at temperatures above 152° C. (305.6° F.), and dissolves in alkalis with yellow color, changing at the same time into *anemonic acid*, $\text{C}_{10}\text{H}_{10}\text{O}_5$. Hanriot (*J. C. S.*, 1887, 843) has further studied anemonin. He finds that it melts at 156° C. (312.8° F.) and decomposes at 270° C. (518° F.) with partial sublimation. With zinc dust or hydriodic acid in sealed tubes, a small quantity of a hydrocarbon is formed which appears to be cymene or cumene. If anemonin be dissolved in chloroform and treated with excess of bromine, it will yield the compound $\text{C}_{10}\text{H}_8\text{Br}_4\text{O}_4$; this crystallizes from benzene in octohedra which do not melt without decomposition. When treated with nascent hydrogen in an acid solution, anemonin yields *hydroanemonin*, $\text{C}_{10}\text{H}_{12}\text{O}_4$, which crystallizes from boiling petroleum in large colorless lamina which contain 1 molecule of H_2O , melt at 78° C. (172.4° F.), and distil without decomposition at from 210° to 212° C. (410°–414° F.) under a pressure of 10 Mm. Hydroanemonin is much more stable than anemonin.

Medicinal Properties and Uses.—*Pulsatilla* is a violent irritant, producing when taken in sufficient amount excessive vomiting and purging, with pain, hæmaturia, tremors, dyspnoea, and collapse. The statements of the physiological action of anemonin vary so much that there can be little doubt that different experimenters have used different substances under the same name. Noel and Lambert (*A. J. P.*, 1897) affirm that it has no action upon the heart but affects powerfully the central nervous system, producing in the lower animals progressive paralysis of spinal origin. On the other hand, Bronevski (*Med. Press*, Aug. 1886) affirms that anemonin affects very powerfully not only the nerve centres but the heart itself. The strength of commercial anemonin is variable. Broudeest gives the fatal dose for the rabbit as 200 Mgm. per kilo, while in Noel and Lambert's experiments 0.16 gramme per kilo was required to kill the guinea pig. Authors place the dose for man at from five-sixths to one and one-half grains (0.05–0.096 Gm.) a day, in divided amounts.

It has been claimed for *pulsatilla* that it acts powerfully upon the genitalia in men and women, and is useful in *dysmenorrhœa* and *ovarian irritation*; also *epididymitis* and *orchitis*. Our own experience with it is in accord with that of many practitioners,—that unless given in infinitesimal dose, with much ceremony, it fails to achieve any good in these various cases, so that the effect which sometimes follows its use in hysterical

women is of psychical origin. Noel and Lambert especially commend a fluidextract made from the fresh herb, of which they state that from seventy-five to one hundred and twenty-five minims (4.6–7.8 Cc.) may be exhibited in the course of twenty-four hours. The dose of the dried powder is commonly given as from two to three grains (0.13–0.2 Gm.), but probably much larger amounts can be safely taken.

Pumice Stone. *Pumex.* *Obsidian.*—A very light porous stone, found in the vicinity of active and extinct volcanoes, and believed to have been thrown up during their eruption. The spongy structure of pumice is believed to be due to the effects of aqueous vapor upon lava while in a fluid state. The pumice stone of commerce is said to be obtained chiefly from Lipari. It is used whole, in the manner of a file, for removing the outer surfaces of bodies, or for rubbing down inequalities, and, in the state of powder, for polishing glass, metals, stones, etc., purposes to which it is adapted by the hardness of its particles. (See *P. J.*, 1882.)

Pural.—Powdered wood charcoal is saturated with a mixture of menthol, phenol, and benzoic acid, and compressed into cylinders. The latter when dried are ignited by a flame and used for disinfecting rooms.

Purgatol. *Purgatin.* *Anthrapurpurine-diacetate.* *Diacetyl Ester of Anthrapurpurine,* or *Tricoxyanthraquinone.* $C_{14}H_5(OH)(OC_2H_3O)_2O_2$. This substance occurs as an orange-colored crystalline powder, melting at 175° to 178° C. (347° – 352.4° F.), insoluble in water and in dilute acids, but slowly soluble in weak alkali and splitting up with development of a deep violet-red coloration.

Purgatol is said to be a laxative similar to emodin, to which it is chemically allied. It is absorbed to some extent, causing the urine to become red. It has been specially recommended in *chronic constipation* in doses of eight grains (0.5 Gm.), increased if necessary, and is said to act in from three to twelve hours without pain.

Pycnanthemum. *Koelia flexuosa* (Walt.), MacM. (*Origanum flexuosum*, Walt., *Pycnanthemum unifolium*, Pursh.) *Dysentery Weed.* This American mint is popularly used in bowel complaints; its hot infusion is diaphoretic. (See *A. J. P.*, 1894, 65, 169; *Ph. Rund.*, 1896, 32.)

Pyramidon. *Di-methyl-amido-phenyl-dimethyl-pyrazolon.*—This is a derivative of antipyrine in which an H atom of the pyrazolon group is replaced by a dimethyl-amido group. It is said to be formed by reducing iso-nitroso-antipyrine and methylating the product so obtained. Pyramidon is a yellowish-white crystalline powder, soluble in water to the extent of 1 in 10 (maximum of solubility is reached at 80° C., 176° F.), and practically tasteless. Pyramidon may be easily distinguished from antipyrine by its color reactions with various reagents. Ferric chloride gives a deep blue-violet fugitive color, and not the red of antipyrine. Nitrous acid gives a fugitive violet instead of the more permanent green of iso-nitroso-antipyrine. Nitric acid also gives a violet to amethyst coloration. In the urine pyramidon may best be detected by ferric chloride, although the color produced is no longer a pure blue, but Tokay red with a tinge of amethyst.

Filehne (*B. K. W.*, 1896) states that pyramidon resembles in its action antipyrine, and is equally efficient as an antipyretic and analgesic, but affirms that it is much more active and that its effects are

more lasting than those of antipyrine. It is readily absorbed and is said to be eliminated through the kidneys in part unchanged, in part converted into *rubaronic acid*, and in part into a material which is colored deeply by ferric chloride and is probably *antipyril urea*. According to Ssadowski it is a stimulant to the heart and blood vessels, so that in phthisis with high arterial pressure it may produce *hæmoptysis*. It has been used as an antipyretic and as an analgesic. As an antipyretic its influence is slow and continuing, and some observers assert that it is more prone than antipyrine and acetphenetidin to produce excessive sweating and collapse. It has been highly commended in *migraine*, *neuralgia*, and similar conditions; also in *asthma* of nervous origin. The statements of Filehne are confirmed by Horneffer (*B. K. W.*, xxxiv, 1897), who further says that he has given it daily for two months without any disagreeable results. The dose, from five to twenty grains (0.32–1.3 Gm.), may be repeated every three or four hours, not exceeding forty grains (2.6 Gm.) in the twenty-four hours, administered in capsule or in aromatic solution.

Pyramidon Camphorate. *Pyramidonis Camphoras.* *Pyramidon Bicamphorate.* *Pyramidonis Bicamphorus.*—It is asserted that the union of camphoric acid with pyramidon markedly lessens its tendency to produce sweating, so that it may be used as an antipyretic, and the bicamphorate has been strongly recommended as an antihidrotic in the night sweats of phthisis.

Pyramidon Salicylate. *Pyramidonis Salicylas.* This substance has been proposed as a substitute for the older salicylates, and may be used in their stead in subacute and chronic cases. The dose of any of these preparations of pyramidon is eight to twelve grains (0.5–0.78 Gm.).

Pyrantin. *p-ethoxyphenylsuccinimide.* *Pheno-succin.* $\begin{matrix} CH_2-CO \\ | \\ CH_2-CO \end{matrix} \backslash N-C_6H_4-OC_2H_5$. It is pre-

pared by melting together *p*-amidophenetol hydrochloride or acetphenetidin with succinic acid and extracting with alcohol. It is colorless, crystallizes in needles melting at 155° C. (311° F.), is insoluble in ether, but soluble in 83.6 parts of boiling water and in 1317 parts of water at 17° C. (62.6° F.). Alkalies convert it into salts of *p*-ethoxyphenylsuccinamic acid, which are soluble in water. A. Piutti states that this drug possesses properties analogous to acetphenetidin. Renzi and De Giovanni have found it especially useful in acute *rheumatism* in doses of from fifteen to forty-five grains (1–3 Gm.) per day. It is said to have no action on the cardiac, respiratory, or digestive organs. (*Chem. Ztg.*, xx.)

Pyranum. *Pyrenol.* *Thymol-sodium Benzoyloxybenzoate.*—This is a white, hygroscopic, crystalline powder with an aromatic odor and a sweetish taste. It dissolves readily in water, one part to five, and in alcohol, one part to ten. This substance, which apparently undergoes change in the system (salicylic acid and thymol having been detected in the urine after its administration), was brought forward by Schlesinger (*Th. M.*, Feb. 1903) as an antipyretic and antineuralgic. Fifteen grammes given to a healthy man in three days produced no other symptoms than sweating, and in the animal large doses caused only a slight fall in the arterial pressure. It was used in various cases of chronic and acute fevers; was found to be superior to salicylic acid in acute

rheumatism, and to have very remarkable analgesic properties. *Dose*, fifteen grains (1 Gm.) repeated up to forty-five grains (3 Gm.) in a day, if required.

Pyrazole. $C_4H_4N_2$. $\left(\begin{array}{l} CH=CH \\ CH=N \end{array} \right) NH$.—This compound has been prepared by acting upon epichlorhydrin with hydrazine in the presence of zinc chloride. It is a basic substance, crystallizing in needles, melting at 70° C. (158° F.), and boiling at 188° C. (370.4° F.). It is readily soluble in water, alcohol, and ether. All of the pyrazole derivatives were found by Tappeiner (*A. E. P. P.*, 1891) to act as paralyzants of the central nervous system. Only one of them, *phenylmethylpyrazol-carboxylic acid*, seems to promise value in practical medicine, on account of its extraordinarily active diuretic effects upon both the lower animals and man. *Daily dose*, from fifteen to thirty grains (1.0–2.0 Gm.).

Pyridine. C_5H_5N .—Pyridine is the first of a series of homologous bases which are found in coal tar naphtha, in shale oil, in peat tar, in tobacco smoke, and more especially in the product known as *Dippel's oil*, obtained by the distillation of bones and other animal matter. It has been used as an antiseptic and germicide, and is employed in Germany for "denaturing" alcohol for manufacturing uses. Pure pyridine is a colorless liquid, with a powerful and persistent odor, of sp. gr. 0.9858 at 0° C. (32° F.), and boils at 115° C. (239° F.). It is miscible with water in all proportions, but is precipitated from its solution by excess of sodium hydroxide. It is also miscible with alcohol, ether, chloroform, benzene, and fatty oils. In toxic dose pyridine is a violent poison, producing cyanosis, methæmoglobinæmia, great muscular weakness from paralysis both of the motor centres and nerves, and finally death from failure of respiration. De Renzi asserts that in small doses it stimulates the heart, increases the blood pressure, and is a useful remedy in angina pectoris. It was first introduced into practical medicine, as a remedy for *asthma*, by Germain Sée, whose statement has since been confirmed by various clinicians. Sée employed it by exposing about a drachm upon a plate in a small room, in which the patient remained from twenty to thirty minutes, the process being repeated several times a day; or from five to fifteen minims in two ounces of water may be taken by an atomizer; or five minims may be inhaled directly. De Renzi has given it internally in the daily dose of six minims gradually increased to twenty-five.

Pyridine Tricarboxylic Acid. $C_5H_2(COOH)_3N$. This important derivative of pyridine may be prepared by the oxidation of methyl-pyridine (picoline), or is obtained from certain natural alkaloids, such as quinine, quinidine, and cinchonidine, by boiling with an alkaline solution of potassium permanganate. It forms prisms melting at 244° C. (471.2° F.). This substance is said to be an active antiseptic and antipyretic, and, according to Rademaker, in malarial fever even surpasses quinine, when given in dose of ten grains (0.65 Gm.) after the paroxysm. The same authority asserts that, when given in doses of from one to two grains (0.065–0.13 Gm.), it will arrest the paroxysm of spasmodic *asthma*. It has also been used in *typhoid fever* as an antipyretic, and as a specific in *gonorrhœa*, when it is given by injection. (*Medical Herald*, June, 1887, 1888.) No accidents have been reported from its use.

Pyrosal.—*Antipyrine salicyl-acetate* forms colorless needles or plates of an acid but not bitter taste which are difficultly soluble in water. Pyrosal is said to contain about 50 per cent. of antipyrine, 36 per cent. of salicylic acid, and 14 per cent. of acetic acid. It is asserted to be broken up in the intestinal canal into its constituents, and to exert their influence in the human system, and has been used in *polyarthritides*, severe *influenza*, *febrile cystitis*, *migraine*, and *sciatica*, in doses of from eight to fifteen grains (0.5–1.0 Gm.), from two to six times daily.

Quebracho Colorado and **Quebracho Gum** are respectively the wood and the dried juice or aqueous extract of the *Lowopterygium Lorentzii* (Fam. Anacardiaceæ), a large tree growing in the Argentine Republic. The wood is very heavy, hard, and of a reddish-brown color. (See *A. J. P.*, 1879, p. 152; also Penzoldt, *loc. cit.*; *P. J.*, xii.) Quebracho colorado has been used as a substitute for the true quebracho, but is essentially different from it, and probably is a simple astringent and gastro-intestinal stimulant, although Penzoldt claims that it is similar in its action, but much weaker than quebracho blanco. Perkin and Gunnel have determined the yellow coloring matter of the wood of quebracho colorado to be identical with *fisetin*, $C_{15}H_{10}O_6$, the coloring matter of young *fustic*, *Cotinus Cotinus* (L.), Karst. It occurs in glistening yellow needles, dyeing similarly to quercetin, and yields compounds with mineral acids. Its benzoyl and acetyl derivatives have also been prepared. Fused with alkalis it yields protocatechuic acid and probably resorcinol. Ellagic and gallic acids have also been obtained from the wood, these being probably formed during the isolation of the *fisetin*. (*A. J. P.*, Nov. 1896, 626.)

Quina Morada.—This drug, growing in Bolivia and the Argentine Republic, and there credited with the therapeutic values of cinchona, is produced by *Chrysocylum* (*Pogonopus*, Kl.) *febrifugum*, O. Kze. (Fam. Rubiaceæ.) It has been studied by Arata and Canzoneri, who find in it a blue fluorescent substance, *moradin*, and an alkaloid, *moradine*. (*P. J.*, April, 1890.)

Quinacetine Sulphate. $(C_{27}H_{31}N_3O_2)_2H_2SO_4 \cdot H_2O$.—This is obtained by the reaction of certain organic compounds with methoxylated di-tetrahydro-chinoly. It is a colorless, odorless, and tasteless powder, and dissolves readily in acidulated water. It is antipyretic and anodyne.

Quinic Acid. *Acidum Quinicum.* *Quinic Acid.* *Hexahydro-tetraoxybenzoic Acid.* $C_6H_8O_7(OH)_4COOH$.—Forms colorless rhombic prisms, easily soluble in water, difficultly soluble in strong alcohol, which fuse at 162° C. (324° F.) Found naturally in cinchona bark, in the coffee bean, and other sources. Led by the belief that the decrease in the elimination of uric acid, which is said to be produced by strawberries, is due to quinic acid, Weiss of Basel, experimentally determined that quinic acid checks the formation of uric acid in the body, and was led to propose it and its salts as remedies in the treatment of *gout*. This theory of the action of quinic acid is certainly not established and of doubtful correctness, but has given rise to practical trials of quinates by various clinicians in *gout* with asserted good results. Quinic acid is converted in the system, first into benzoic, and second into hippuric acid. Various combinations of quinic acid have appeared in commerce, often under proprietary names. The most important are the following:

Chinotropin. Hexamethylenetetramine Quinate. It is claimed for this combination of quinic acid and hexamethylenetetramine that it is superior to quinic acid alone in many cases, because of the decomposition of the hexamethylenamine in the system with the formation of formaldehyde and consequent reactions of that body with uric acid resulting in soluble compounds. It appears to be specially useful in cases of *gouty diseases* of the urinary tract.

Piperazine Quinate. Piperazine Kinate (Sidal).—The quinates of piperazine and its derivatives, such as dimethylpiperazine, are white crystalline powders which are of slight taste and are soluble in water. They form salts with the alkali metals when their aqueous solutions are mixed with alkaline carbonate and evaporated. It is claimed that they exert the activity of quinic acid and of piperazine in *gout*, restraining the production of uric acid and causing the formation of hippuric acid in the organism. It is asserted that, while this substance gives brilliant results in the treatment of *gout*, especially during the attack, it is of little value in articular rheumatism. *New sidonal* is the salt of an inner anhydride of quinic acid which changes in the intestines and blood readily into quinic acid. Piperazine quinate is a white powder, freely soluble in cold water, which is given in doses of from seventy-five to one hundred and twenty grains (5–7.7 Gm.) per day. Richter found that the deposits of uric acid which are produced in pigeons by injecting potassium chromate were prevented by the simultaneous administration of sidonal, and a number of observers have reported excellent results, both in acute and chronic *gout*, from the use of the remedy.

Quinotropine. Urotropine Quinate.—This quinic compound is furnished commercially in two forms, Quinotropine I, containing 73 per cent. quinic acid and 27 per cent. urotropine; Quinotropine II, containing 80 per cent. quinic acid and 20 per cent. urotropine. These compounds yield aqueous solutions of an acid, agreeable taste. According to Nicolaier and Hagenberg (see also De la Camp, *M. M. W.*, 1901, No. 30), quinotropine does not decrease the excretion of uric acid, but aids in its solution in the urine.

Dose, Quinotropine I: fifty-five to eighty grains (3.6–5.2 Gm.) per day; Quinotropine II: seventy-five to one hundred and ten grains (5.0–7.1 Gm.) per day.

Urol, Urea Quinate, a combination of two molecules of urea and one of quinic acid, has the composition $C_7H_{12}O_8 \cdot 2CO(NH_2)_2$; forms prismatic crystals melting at 106° to 107° C. (222.8° – 224.6° F.). It is recommended by Van Noorden in doses of thirty to seventy-five grains (2–5 Gm.) dissolved in a tumblerful of hot water, on rising and going to bed, as a solvent for uric acid.

Urosin.—**Lithium Quinate,** a mixture of quinic acid and lithium citrate, has been put upon the market in the form of tablets which contain 0.5 Gm. of quinic acid and 0.15 Gm. of lithium citrate. Six to ten 5 grain tablets may be given in a day.

Quinine Arsenate. Quininæ Arsenas. $2(C_{20}H_{24}N_2O_2) \cdot H_3AsO_4 + 8H_2O$.—Made by precipitating a solution of 10 parts of quinine hydrochloride in 200 parts of water with a solution of 3.9 parts of sodium arsenate dissolved in 100 parts of water. The precipitate is washed and purified by recrystallization. In white prismatic crystals, slightly soluble in cold water, very soluble in hot

water. The salt contains 69.39 per cent. of quinine and 12.30 per cent. of arsenic acid. **Dose,** one to three grains (0.065–0.20 Gm.).

Quinine Benzoate. Quininæ Benzoas. $C_{20}H_{24}N_2O_2 \cdot C_7H_5O_2$.—It may be made by neutralizing 3 parts of benzoic acid, dissolved in hot alcohol, with 8 parts of anhydrous quinine and crystallizing. The salt contains about 73 per cent. of quinine. Difficultly soluble in water, requiring about 370 parts for solution.

Quinine Borate. Quininæ Boras. $C_{20}H_{24}N_2O_2 \cdot H_3BO_3$.—Mix 10 parts of anhydrous quinine and 1.91 parts of boric acid with 20 parts of water, evaporate and powder the dried residue. The salt contains about 84 per cent. of quinine.

Quinine Bromate. Quininæ Bromas. $C_{20}H_{24}N_2O_2 \cdot HBrO_3$.—Made by salifying quinine with hydrobromic acid. It forms needle-like masses of crystals, is soluble in about 250 parts of cold water, freely in warm water and in alcohol.

Quinine Carbonate. Quininæ Carbonas. $C_{20}H_{24}N_2O_2 \cdot H_2CO_3 + H_2O$.—The carbonate is made by passing carbon dioxide through a mixture, in which freshly precipitated quinine is suspended, until all the quinine is dissolved; the solution is then evaporated and crystallized.

In the form of fine, needle-like crystals, soluble in water and alcohol.

It contains 73.66 per cent. of quinine.

Quinine Chlorhydrophosphate. Quininæ Chlorhydrophasas. $C_{20}H_{24}N_2O_2 \cdot HCl (H_3PO_4)_2 + 3H_2O$.—The salt is made by dissolving 35 parts of quinine hydrochloride in a mixture of 70 parts of 25 per cent. phosphoric acid and 9 parts of 12.5 per cent. hydrochloric acid and allowing the crystals to form during spontaneous evaporation. Soluble in about 2 parts of water, having an acid reaction, and containing about 53 per cent. of quinine.

Quinine Chlorhydrosulphate. Quininæ Chlorhydrosulphas. $(C_{20}H_{24}N_2O_2)_2 H_2SO_4 (HCl)_2 + 3H_2O$.—Made by dissolving 10 parts of quinine sulphate in 3.3 parts of 25 per cent. hydrochloric acid and allowing the solution to crystallize during spontaneous evaporation. It forms colorless crystals, soluble in 1 part of water. The salt contains about 74 per cent. of quinine.

Quinine Chromate. Quininæ Chromas. $C_{20}H_{24}N_2O_2 \cdot H_2CrO_4 + 2H_2O$.—It may be made by precipitating 4 parts of quinine hydrochloride, in 100 parts of warm water, with 1 part of neutral potassium chromate, dissolved in 15 parts of water. The crystals are washed and purified by recrystallization from hot diluted alcohol. In the form of yellow crystalline needles, almost insoluble in cold water, soluble in 160 parts of boiling water.

Quinine Eosolate. Quininæ Eosolas. $C_9H_7S_3 O_{12} (C_{20}H_{24}N_2O_2)_2$.—This is the commercial name of the neutral quinine salt of *trisulpho-acetylcreosote*. Very active anti-periodic properties have been claimed for it. **Dose,** three grains (0.2 Gm.) three times a day.

Quinine Glycerophosphate. Quininæ Glycerophosphas.—*Kineurine*, $C_8H_7O_3PO_3 (C_{20}H_{24}N_2O_2)_2$, forms a white powder, soluble in hot water and alcohol, which contains 68 per cent. of quinine in combination with glycerophosphoric acid. This substance has been recommended as an anti-periodic in doses of five to ten grains (0.32–0.65 Gm.). The tonic dose is set down as one and one-half to three grains (0.096–0.2 Gm.).

Quinine Iodate. Quininæ Iodas. $C_{20}H_{24}N_2O_2 \cdot HIO_3$.—Made by dissolving freshly precipitated

quinine in hydriodic acid, using molecular proportions, and afterwards evaporating and drying the salt. In small needle-like crystals, freely soluble in alcohol and in 700 parts of cold water. It contains about 63 per cent. of quinine.

Quinine Phenolsulphonate. *Quinine Phenolsulphonas. Quinine Sulphocarbonate.* $\text{C}_{20}\text{H}_{24}\text{N}_2\text{O}_2$ $[\text{C}_6\text{H}_4(\text{OH})\text{SO}_3\text{H}]$.—Made by precipitating 10 parts of quinine sulphate, in 500 parts of water, by adding it to a boiling solution of 6 parts of barium phenolsulphonate, dissolved in 75 parts of water. The precipitate is washed and dried. A yellowish-white mass, melting when warmed, only slightly soluble in water, soluble in alcohol.

Quinoa.—The *Chenopodium Quinoa*, Willd. (Fam. Chenopodiaceæ), is largely cultivated in Southern Peru and Southern Chili, often above the height at which barley and rye will ripen, for the sake of its seeds. These are about the size of white mustard seeds, but flatter, and afford a flour resembling somewhat oatmeal. The starch grains are very small, and constitute about 40 per cent. of the grain, which also contains 5 per cent. of sugar, $7\frac{1}{2}$ of casein, and 11 of albumen and other protein compounds. One variety, the red quinoa, contains a bitter principle in the seed husks, and is used to some extent as an emetic and antiperiodic. (A. J. P., 1872, 559.)

Quinoline Bismuth-Sulphocyanate or Rhodonate. *Quinoline Bismuth-Sulphocyanas.*—A granular, reddish-yellow powder, insoluble in water, alcohol and ether, melting at 70°C . (158°F .).

Quinoline Sulphocyanate or Rhodonate. *Quinoline Sulphocyanas.*—A colorless or yellowish, crystalline powder, only slightly soluble in cold water and ether, but freely soluble in hot water and alcohol. The salt melts at about 137°C . (278.6°F .).

Radium.—*History and Discovery.*—The fact that pitch blende, the native uranium mineral, gives out rays, which act upon photographic plates when the latter are wrapped in black paper, cause certain phosphorescent substances to become illuminated and make air through which they pass a conductor of electricity, was discovered by the physicist Becquerel. These properties were found to be possessed by all the uranium and thorium minerals as well as by the metals themselves. In 1897 Madame Curie began an investigation of the relative activity of the various salts of uranium and later of the minerals containing that element. While she found that the radio-activity of the different uranium and thorium salts was always less than that of these two metals themselves, yet certain native uranium and thorium minerals possessed these properties in a notably higher degree than either of the metals first mentioned. She was therefore led to the conclusion that these minerals contained one or more new elements to which this property belonged in a much higher degree than to uranium or thorium.

Physical and Chemical Properties.—The extraction of radium salts from the residues of the pitch blende remaining from the working of it for uranium is a long and tedious process, one ton of the residues having finally yielded a few decigrammes of a substance resembling barium. This was, however, many thousand times as active as uranium. After radio-active barium bromide is obtained, 60 times more active than metallic uranium, the bromide is subjected to a long series of crystallizations dependent upon the fact that radium bromide is less soluble in water than the

barium bromide. The element itself has not yet been obtained, although radium amalgams have been prepared, its chloride, bromide, carbonate, nitrate and sulphate resemble similar barium salts.

Radium bromide, however, shows a characteristic spectrum and colors the Bunsen flame carmine-red. All radium salts are luminescent and excite phosphorescence in a variety of chemical compounds and minerals. This power is notably shown upon zinc sulphide and barium platinocyanide. Photographic plates covered with black paper are also at once affected. Radium compounds also bring about many chemical decompositions and exert notable physiological effects upon vegetable and animal organisms.

Most remarkable, however, is the fact that radium compounds show what is apparently evidence of continuous breaking up without any extraneous inciting cause. By reason of this decomposition radium salts spontaneously develop heat and in consequence always show from 3° to 5°C . higher temperature than surrounding objects. It is estimated that one gramme of radium will thus emit in a day 2400 or in a year 876,000 gramme calories.

In connection with this decomposition, radium is capable of giving off rays or emanations which have been respectively designated as α , β , and γ rays, all of which differ in their physical characters. Of these rays, the α -rays are easily absorbed, the β -rays are the same as the cathode rays, and the γ -rays in some respects resemble the Roentgen rays. Ramsay and Soddy submitted the radium emanations to a spectroscopic investigation and discovered that the emanation could be in part condensed by the aid of liquid air, and that this portion in a few days changed into the element helium. Chemists have been led therefore very generally to accept at least provisionally the theory of Rutherford and Soddy that radio-activity is an atomic and not a molecular property and that the atoms of certain elements of high atomic weight, which alone show radio-activity, undergo spontaneous disintegration.

Metallic radium has, as before stated, not as yet been isolated. By the analysis of the purest of its salts, however, the atomic weight 225 has been deduced for it. Two other rare elements have been also indicated as present in the residues from pitch blende, viz.: *polonium*, the salts of which were obtained by Madame Curie in 1898, and *actinium*, announced by Debierne in 1899. Besides these three, the only other known radio-active elements are uranium and thorium. All of these elements have very high atomic weights and all are supposed to show by their emanations evidence of atomic disintegration.

Physiological Action, Therapeutic Applications, and Uses.—The therapeutic properties of radium appear to be very similar to those of the X-ray. A moderate exposure to the radium produces an inflammatory reaction, which after more prolonged or severe exposure leads to a destruction of tissue. London (B. K. W., xliii.) found that rabbits kept for two weeks in a cage on top of which was placed 25 mgm. of radium lost their hair, the ears necrosed and the sexual organs degenerated; he believes that the emanations have no effect on fibroid tissue. The therapeutic value of the substance seems to be due to the fact that diseased tissue is more susceptible to the radium rays than healthy, so that the chief utility is for the purpose of destroying morbid growths, as *epitheliomata*, *lupus*, *rodent ulcers* and

the like. It was at one time hoped that radium would offer a means of treating the deeper cancers which are beyond the reach of the X-ray; unfortunately, however, the radium emanations do not appear to have any greater penetrative powers; according to Metzenbaum (*N. Y. M. R.*) even when tubes of radium are placed within large carcinomata there is produced merely a local change. On the other hand in certain cavities, as the mouth, rectum, or vagina, the ease with which radium can be brought in contact with the disease focus gives the element a distinct place in therapeutics.

As regards the dosage no definite statement can be made; the amount employed must be governed by the effects. It must be remembered that radium is a powerful substance capable of much harm and should be applied only by those with special skill.

Raisins. *Uva Passa*. U. S. 1870.—The dried ripe fruit of the *Vitis vinifera*, L. (Fam. Vitaceæ), is no longer recognized by the Pharmacopœia. The grape vine itself is too well known to require description. Its leaves and tendrils are somewhat astringent, and were formerly used in *diarrhœa*, *hemorrhages*, and other morbid discharges. The juice which flows from the stem was also thought to be possessed of medicinal virtues, and the idea still lingers among the vulgar in some countries. The unripe fruit has a harsh sour taste, and yields by expression a very acid liquor, called *verjuice*, which was much esteemed by the ancients as a refreshing drink when diluted with water. It contains malic and tartaric acids, and an acid called *racemic acid*, a compound isomeric with tartaric acid, but differing from it in being optically inactive. M. A. Petit has ascertained that grape leaves contain 2 or 3 per cent. of glucose, and a quantity of acid varying from 1.3 to 1.6 per cent. Of the acid, tartaric acid constituted one-third, and most of this was in the form of cream of tartar. In a subsequent investigation, Petit found that, besides glucose, or sugar of grapes, the leaves contained a notable portion of common or cane sugar. In one instance he secured 0.97 per cent. of cane sugar and 2.665 of glucose; in another, in which he operated so that the common sugar in the leaves had less opportunity to be converted into glucose, he obtained 1.58 per cent. of the former and 1.749 of the latter. (*J. P. C.*, Janv. 1874, 41.) The seeds afford from 15 to 18 per cent. of a bland fixed oil, which is occasionally extracted. Fitz (*Ber. d. Chem. Ges.*, 1871, 442) has shown that it consists of the glycerides of *erucic acid*, $C_{22}H_{42}O_2$, stearic and palmitic acids, the first-named acid largely prevailing. The seeds further contained from 5 to 6 per cent. of tannic acid, which also exists in the skin of the fruit. The grape, when quite ripe, is among the most pleasant and grateful fruits, and is admirably adapted, by its refreshing properties, to febrile complaints. If largely taken, it proves diuretic and gently laxative. The ripe fruit differs from the unripe in containing more sugar and less acid, though never entirely destitute of the latter. The plant is supposed to have been derived originally from Asia; but it has been cultivated in Europe and Northern Africa from the remotest antiquity, and is now spread over all the temperate civilized regions of the globe. The fruit is exceedingly influenced by soil and climate, and the varieties of the plant which have resulted from culture or situation are innumerable.

Several varieties of raisins are known in commerce. The best of the European fruit are the *Malaga raisins*, imported from Spain. They are large and fleshy, of a purplish-brown color and sweet agreeable taste. Those produced in Calabria are similar. The *Smyrna raisins* are also large, but of a yellowish-brown color, slightly musky odor, and less agreeable flavor. They are originally brought from the coast of Syria. The *Corinthian raisins*, or *currants* as they are commonly called in this country, are small, bluish black, of a fatty appearance, with a vinous odor and a sweet, slightly tartish taste. Their name is derived from the city in the vicinity of which they were formerly cultivated. At present they are procured chiefly from Zante, Cephalonia, and the other Ionian Islands. In the older Pharmacopœias they are distinguished by the title of *uvæ passæ minores*. Within recent years the production of raisins in California has become an industry of the highest importance. According to official reports, the California raisin crop for 1902 was 108,000,000 pounds. These raisins are coming into large use in the United States and are rapidly replacing those obtained from Malaga; the importation of the latter has decreased in the years between 1876 and 1900 at least 90 per cent. The ripe grapes are cut from the vines, spread out on a clay floor, and dried by exposure to the heat of the sun. The drying process usually requires about ten days' time. Artificial heat is used to dry them in rainy weather; sometimes the grapes are partially dried on the vines; this is done by cutting the stalks of the ripe grapes half way through, and allowing the bunches to remain for a few weeks, a portion of the bark of the vine being removed also to facilitate the process. If it is desirable to remove the waxy bloom on the grapes, the bunches are steeped for a short time in weak alkaline solution, washed and then thoroughly dried.

Raisins usually contain more sugar than do recent grapes. This principle, indeed, is often so abundant that it effloresces on the surface or concretes in separate masses within the substance of the raisin. The average composition of the raisin is given as 32.02 per cent. water, 2.42 nitrogenous material, 0.59 fat, 54.56 sugar, 7.48 other nitrogenous organic matter, 1.72 wood fibre, and 1.21 ash. (König, *Nahrungs- und Genussmittel*, 3te Aufl., ii. 815.) The sugar of grapes (*glucose*) differs from that of the cane, being less sweet, less soluble in cold water and much less so in alcohol. In these respects it does not differ from artificial glucose, which is now made in enormous quantities and consumed in food products and candies; the artificial product is made by acting on starch with sulphuric acid (see page 1071).

The chief medicinal use of raisins is to flavor demulcent beverages. Taken in substance they are gently laxative, but are also difficult of digestion, and, when largely eaten, sometimes produce unpleasant effects, especially in children.

Randia. *Randia dumetorum*, Lam. (Fam. Rubiacæ).—The fruit of this East India shrub is used by the natives as a fish poison, and is said to act in man as an irritating emetic. According to the *Pharmacographia Indica*, each fruit contains about four grains (0.26 Gm.) of saponin, besides valeric acid. The tincture has been used by James Sawyer (*L. L.*, 1891) as an antispasmodic.

Ranunculus. *Crowfoot*. *Renoncule*, Fr. *Hahnenfuss*, G.—Most of the plants belonging to the genus *Ranunculus* have similar acrid prop-

erties, and, from their close resemblance, are founded under the common name of *buttercup*. *R. bulbosus*, L., was formerly on the Secondary List of the U. S. Pharmacopœia; but *R. sceleratus*, L., had attracted more attention in Europe, and *R. acris*, L., and *R. flammula*, L., were recognized by the Dublin College. In all these species the plant itself is a violent irritant, producing when chewed excessive inflammation in the mouth and throat, and, when swallowed, toxic gastritis which may be fatal. The acrid principle appears to be volatile; according to Bigelow, it is yielded to water in distillation. Clarus discovered, in *R. sceleratus*, L., besides the acrid volatile oil, a nearly inert resin, and a narcotic principle called *anemonin* or *anemone camphor*, $C_{15}H_{12}O_6$. The volatile oil is soluble in ether, and is decomposed, on standing, into a white amorphous substance having acid properties (*anemonic acid*), $C_{15}H_{14}O_7$, and into *anemonin*. (*Brit. and For. Med.-Chir. Rev.*, 1859, 181.) Rochebrune states that he has separated from *R. aquatilis*, L., *R. flammula*, L., *R. sceleratus*, L., and *R. bulbosus*, L., crystalline alkaloids to which he has given the name of *ranunculine*, although their identity is doubtful. These alkaloids are violent irritants and active cardiac poisons. (*Toxicolog. Africaine*, i.) Before the introduction of cantharides the green buttercup plants were much employed as vesicants.

Realgar. As_2S_3 . *Red Orpiment*.—This is *arsenic disulphide*. It is found native in Saxony, Bohemia, Transylvania, and in various volcanic regions. Realgar is artificially made by melting arsenic trioxide with about half its weight of sulphur. Thus prepared, it is of a crystalline texture, of a beautiful ruby-red color, of a uniform conchoidal fracture, somewhat transparent in thin layers, and capable of being sublimed without change. Native realgar is said to be innocuous when taken internally, while that artificially prepared is poisonous, in consequence, according to Guibourt, of containing a little free arsenic trioxide. Realgar is used only as a pigment.

Red Chalk. Reddle.—A mineral substance of a deep red color, of a compact texture, dry to the touch, adhering to the tongue, about as hard as chalk, soiling the fingers when handled, and leaving a lively red trace when drawn over paper. It consists of clay and ferric oxide, and is intermediate between *bole* and *red ochre*, containing more ferric oxide than the former and less than the latter. It is used for drawing lines upon wood, etc., and is sometimes made into crayons by levigating and elutriating it, then forming it into a paste with mucilage of gum arabic, moulding this into cylinders, and drying it in the shade. It has been used internally as an absorbent and astringent.

Regianin.—This is a principle obtained by Phipson from the nut of *Juglans regia*. It occurs in octahedral, prismatic, or feathery crystals, and gives with ammonia and other alkalies a reddish-purple solution, from which hydrochloric acid precipitates an amorphous powder, *regianic acid*. It is probably identical with the *nuçin* obtained from green walnut shells.

Rennet. *Gastric Juice. Liquor Seriparus. Laabessenz*, G.—For a full account of the constitution of gastric juice and its properties the reader is referred to works upon physiology. The crude juice was applied by P. S. Physick to foul ulcers. *Rennet* is an aqueous or vinous infusion of the dried stomach of the calf, though

that of the sheep or other animal would probably answer the same purpose. It is much used, as every one knows, for curdling milk, a property which it owes to a portion of the gastric secretion, retained and dried in the mucous tissue of the stomach. To the same material it probably owes the property which it possesses of converting glucose into lactic acid, and there is little doubt that it is capable, in greater or less degree, of exercising the solvent property of gastric juice over albuminous and fibrinous food. It is highly probable that the preparation usually employed to curdle milk may contribute to the ready digestibility of the curds and whey. George Ellis prepared *rennet wine* as follows: Take the stomach of a calf immediately after the animal has been killed, cut off and reject about three inches of the upper or cardiac portion, slit the stomach longitudinally, wipe it gently with a dry napkin so as to remove as little of the clean mucus as possible, then cut it into small pieces, the smaller the better, put it into a common wine bottle, fill the bottle with good sherry, and let it stand corked for three weeks. It is known to be good if a teaspoonful will coagulate half a pint of milk in two minutes at 37.7° C. (100° F.). The dose is a teaspoonful in a wineglassful of water, immediately after each meal.

Resaldol. $C_{20}H_{14}O_5$ $(CH_3CO)_2$.—Resaldol is an acetyl derivative obtained by acetylating the product of the reaction between chlormethyl-salicylic aldehyde and resorcinol. It is an amorphous yellowish-brown powder of an astringent taste, insoluble in water and dilute acids, but soluble in alkalies. Its peculiar solubilities led Eichengrün to use it as an intestinal antiseptic, with the expectation that it would escape gastric action and be dissolved in the intestines. It has been tried in *tubercular* and other forms of *intestinal ulcerations* with asserted good results. Dose, forty-five to sixty grains (3-3.9 Gm.), taken in the course of the day, either in powder or capsule.

Resalgin. *Antipyrine Resorcyolate*.—This occurs in crystalline needles soluble in 150 parts of cold water and 20 parts of boiling water, readily soluble in alcohol, ether, and chloroform. It is obtained by acting on antipyrine with potassium resorcyolate. Forms colorless, odorless crystals melting at 110.5° C. (231° F.).

Reseda. *Reseda Luteola*, L. *Weld. Dyer's Weed. Herbe Jaune, Gaude*, Fr. *Wau, Gelbkraut, Harnkraut*, G. (Fam. *Resedaceæ*).—An annual European plant, naturalized in the United States. It is inodorous, and has a bitter taste, which is very persistent. Volhard showed that allyl thiocyanate, C_3H_5SCN (volatile oil of mustard), was present in the root, and Chevreul obtained from it by sublimation a peculiar yellow coloring matter, which he called *luteolin*, and which has the formula $C_{20}H_{14}O_6$. Hlasiwetz and Pfaunder (1895) assign to it the formula $C_{15}H_{10}O_6$. This forms yellow crystals of silky lustre, insoluble in water, soluble in alcohol. It dissolves in alkalies with deep yellow color. It is used especially in silk dyeing. Rochleder and Brenner (*J. Pr. Chem.*, xcix. 433) found that when fused with potassium hydroxide it was decomposed into phloroglucin and protocatechuic acid with evolution of carbon dioxide. A. G. Perkin (*J. Chem. S.*, 1896) investigated the salts of luteolin, and called attention to the similarity of its properties to those of *fisetin*. In medicine it has been employed as a diaphoretic and diuretic, but it is now used only for dyeing purposes.

Resol.—A proprietary disinfectant said to be made by saponifying wood tar with potassium hydroxide and adding wood spirit.

Resorpyrine. $C_{11}H_{12}N_2O + C_6H_4(OH)_2$.—Made by mixing solutions of 30 parts of antipyrine and 11 parts of resorcinol. A crystalline mass separates which should be recrystallized from alcohol. It is insoluble in water.

Resorbin.—An ointment vehicle made by emulsifying almond oil and water by means of a little yellow wax, gelatin, and soap, to which is added some lanolin. It is asserted that it greatly facilitates the absorption of medicaments.

Retamine. $C_{15}H_{28}N_2O$.—This is an alkaloid, crystallizing in long needles, melting at $162^\circ C.$ ($323.6^\circ F.$), with decomposition, which has been isolated by Battandier and Malosse from the young shoots and branches of *Retama sphaerocarpa*, Raf. (*Cytisus sphaerocarpus*, O. Kze.).

Retinol. $C_{32}H_{54}$.—A product obtained by the distillation of Burgundy pitch or resin. It forms a yellowish oil boiling at temperatures over $280^\circ C.$ ($536^\circ F.$). It is stated that retinol does not irritate the skin, is unaltered by light, is mildly antiseptic, does not become rancid, and is very inexpensive; qualities which, taken along with its extraordinary solvent power, bid fair to make it a valuable vehicle for ointments. Among the substances dissolved by it are: salol, 1-10; iodol, 1-50; naphthol, 1-50; thymol iodide, 1-50; camphor, 1-20; chrysophanic acid, 1-40; cocaine, 1-30; codeine, 1-40; and strychnine, 1-40. It is miscible in all proportions with oil of juniper, phenol, turpentine, alcohol, and ether. Resorcinol, if dissolved in glycerin, may be mixed with retinol, and so may iodoform if it be dissolved in a little ether. Iodol is dissolved, but soon precipitates as a resinous mass. Phosphorus is also dissolved, and the solution remains unchanged indefinitely. Retinol mixes readily with fats, oils, vaseline, lard, lanolin, glycerin, cacao butter, etc., and may be used in ointments. In cases where a liquid is not undesirable, retinol, owing to its antiseptic properties, can with great advantage replace these bodies. Upon the mucous membrane retinol seems to act as a mild stimulant antiseptic; it has been used with alleged excellent results locally in *otitis*, *vaginitis*, *rhinitis*, and other mucous diseases. Injections of it in *gonorrhoea* are said to be remarkably effective. As a means of administering phosphorus it is especially recommended.

Rhigolene.—This name was given by H. J. Bigelow of Boston, to a very light, inflammable liquid, obtained by distilling petroleum, and separating the liquids of the lowest boiling point by redistillation, until one is obtained which boils at about $18^\circ C.$ ($64.4^\circ F.$). A degree of cold $-9^\circ C.$ ($15.8^\circ F.$) is, according to Bigelow, obtained through the evaporation of this liquid by means of the common atomizer or "spray-producer." This is the chief use of the liquid, which may be employed in producing congelation of any part of the body preparatory to a surgical operation, or a great degree of cold for any other purpose. It should, when not in use, be kept in a cool place, in bottles tightly corked, or otherwise it will be rapidly evaporated. In a warm place it might break the bottles through its extreme volatility, unless the stopper should previously be driven out. The vapor is inflammable and care should be exercised in using it near a flame.

Rhododendron. *Rhododendron Chrysanthemum*, Pall. *Yellow-flowered Rhododendron*. *Rosebay*.

Snowrose. *Rosage*, Fr. *Alpenrose*, *Schneerose*, *Gichtrose*, G. (Fam. Ericaceae).—The leaves of this rhododendron have long been employed in Siberia as a remedy in *rheumatism*, and to a less extent in *gout* and *syphilis*. They yield their virtue to water and alcohol, and, according to von Archangelski, contain three proximate principles; *rhododendrol*, $C_{20}H_{32}O_2$; *rhododendrin*, $C_{16}H_{22}O_7$; and a glucoside resembling digitalin and very toxic. The dose of the dried leaves is said to be two drachms (7.7 Gm.), given in infusion.

G. F. Kuehnelt found in leaves of the "great laurel," *Rhododendron maximum*, L., *arbutin*, *ericolin*, and *ursone*. (A. J. P., 1885.)

Rhus.—The genus *Rhus* contains various species which have the property—probably even without direct contact—of so violently irritating susceptible skins as to produce severe poisoning. Of these poisonous species there are six which are recognized in the United States by most modern botanists.

R. Vernia, L. (*R. venenata*, DC.).—*Swamp Sumac*, *Poison Sumach*, *Poison Elder*, is a handsome shrub or small tree, usually ten or fifteen feet high, but sometimes thirty feet. The bark of the trunk is dark gray, of the branches lighter, of the extreme twigs and petioles pale to deep red. The leaves are pinnate, with four or five pairs of opposite leaflets, and an odd terminal one. These are oblong or oval, entire or slightly sinuate, acuminate, smooth, and, except the one at the end, nearly sessile. The flowers are dioecious. They are very small, greenish, and in loose axillary panicles. The berries are small, roundish, and greenish white. The tree grows in swamps and low grounds from Canada to Carolina, and flowers in June and July. It was confounded by the older botanists with *R. vernicifera*, DC., of Japan, the Japanese lacquer tree, which has similar poisonous properties. Its activity is said to depend upon *urushic acid*.

Rhus Michauxii, Sargent (*R. Pumila*, Michx.), is a rare Southern species, growing in upper Carolina and Georgia, and not more than a foot in height. It is characterized by its pubescent branches and petioles, by its pinnate leaves, with many pairs of oval, nearly acuminate, incised-dentate leaflets, downy beneath, and by its silky fruit. According to Pursh, it is the most poisonous of the genus.

Rhus diversiloba, Torrey and Gray (*R. lobata*, Hooker, *Flor. Bor. Am.*, i. 127, t. 46), is found on our Pacific border. It is there generally known as *Poison Oak*. It has a somewhat climbing stem, with short, leafy branches. The leaves have three or rarely five leaflets, which are very obtuse, in the female plant slightly, in the male rather deeply pinnately lobed, the lobes being very obtuse, and the incisions acute. The flowers are in axillary, racemose panicles often shorter than the petioles; the fruit is white, somewhat pubescent, and subglobose. The leaves in the male and the female plant are so different that they might readily be mistaken for different species. (Torrey and Gray.) Though generally a shrub, the plant sometimes climbs over large trees, and may have a stem six inches in diameter.

Rhus Metopium, L. (*Metopium Linnaea*, Engelm.), *Mountain Manchineel*, *Coral Sumac*, is a West Indian species, growing also in the "hummock" lands of Southern Florida. It is a small tree, the bark, when wounded, exuding a gum-resin (hog gum) to which medicinal properties

are ascribed. The leaves are pinnate with fine leaflets. To the acid red fruit is due the name Coral Sumac. It is exceedingly poisonous.

Rhus Toxicodendron, L., *Poison Oak*, of the Southern States, is a low, erect plant, the leaflets ovate, mostly obtuse, crenate or crenately lobed, often to the middle, so as to resemble the leaves of an oak; the sinuses sharp, petals about 2 millimeters long, fruit depressed-globose, 6 to 8 millimeters in diameter.

Rhus radicans, L., *Poison Oak*, *Poison Ivy*, whose fresh leaves were formerly official in the U. S. Pharmacopœia under the name of *Rhus Toxicodendron*, U. S. 1890, is a woody vine climbing by numerous aerial rootlets; the leaves petioled, leaflets ovate or rhombic, 2.5 to 15 Cm. long, entire or sparingly dentate or sinuate, acute or short-acuminate, the lateral sessile, acute or stalked, inequilateral, the terminal ones stalked, flowers green, 3 Mm. broad, in loose axillary panicles, 2 to 8 Cm. long; the fruit globose-oblong, gray.

The leaves were officially described as "long-petiolate, trifoliate; the lateral leaflets sessile or nearly so, about 10 Cm. long, obliquely ovate, pointed; the terminal leaflets stalked, ovate or oval, pointed, with a wedge-shaped or rounded base; the leaflets entire and glabrous, or variously notched, coarsely toothed or lobed, more or less downy; when dry, papery and brittle; inodorous; taste somewhat astringent and acrid." U. S. 1890.

The milky juice of the poisonous rhus becomes black on exposure to the air, and leaves upon linen or other cloth a stain, which cannot afterwards be removed by washing with soap and water, or by alcohol either hot or cold, but deepens by age. It has been proposed as an indelible ink. Ether dissolves it; applied to the skin it frequently causes inflammation and vesication.

Analyzed by Joseph Khittel, rhus yielded tannic acid of the variety which gives greenish precipitates with salts of iron, with chlorophyll, wax, fixed oil, resin, sugar, albumen, gum, pectin, starch, oxalic acid, a peculiar neutral substance, and a volatile alkaloid, on which the poisonous properties of the plant were supposed to depend. (A. J. P., 1858, p. 544.) This supposed alkaloid probably does not exist. Maisch thought that the activity of the plant depended upon an acid (*toxicodendric acid*). To obtain this acid, the leaves were bruised with 6 per cent. of slaked lime, and after maceration with water were expressed. The expressed liquid, having been mixed with an excess of sulphuric acid, was distilled, and the vapors were condensed, partly by themselves, so as to obtain the pure acid, and partly in water containing barium carbonate in suspension, so as to get barium toxicodendrate. The solution thus obtained was colorless and strongly acid. (A. J. P., Jan. 1866.) F. Pfaff has obtained Maisch's toxicodendric acid both in the form of barium salt and as free acid in aqueous solution, and found both to be non-toxic. The real active principle he found to be a non-volatile oil. This oil, which he terms *toxicodendrol*, is present in all parts of the plant, whether in a fresh green state or in old and dried specimens. *R. venenata* yields a larger percentage of the oil than *R. radicans*, but no difference was found in the oils from the two. This oil applied to the skin caused the well-known eruption. Pfaff recommends a washing with alcoholic solution of lead acetate, as the oil is soluble in alcohol and forms a lead compound nearly insoluble. (Proc. A. Ph. A., 1895, 843, and 1898, 865.)

The poisonous rhus when taken internally appears to be possessed of narcotic besides irritant properties, vomiting, drowsiness, stupor, dilated pupils, convulsive movements, delirium, and fever having been present in poisoning by them (Am. J. M. S., April, 1866; also M. Rep., Nov. 1867). The tincture of rhus has been used especially by homœopathic practitioners in the treatment of *subacute* and *chronic rheumatism*, and the practice has found imitation.

Some years ago H. C. Wood made extended trials of the remedy, using a homœopathic tincture obtained from a homœopathic pharmacy, in various doses (homœopathic, small, and large), upon a large number of cases of *subacute*, *chronic*, and *acute rheumatism*, in the Philadelphia Hospital, but he was not able to perceive that the patients progressed more rapidly when taking it than when they were simply nursed. The best preparation would undoubtedly be a concentrated alcoholic tincture, made from the green drug; strength of one to four. The dose of a 25 per cent. tincture given by H. C. Wood was from one to five minims (0.06–0.3 Cc.), three times a day. The solid extract is an ineligible preparation, owing to the extreme volatility of the active principle of the crude drug.

For the violent dermatitis which is produced by the poison ivy very numerous specifics have been from time to time proposed. There seems, however, to be no method of treatment better than the use of lead water and laudanum. If the belief of Pfaff be correct, that the acrid substance is a fixed oil, thorough washing and irrigation of the part with a diluted solution of sodium carbonate would seem to be indicated for the removal of the irritant.

Rhus aromatica, Ait. (Fam. Anacardiaceæ.) This indigenous drug has been highly recommended in the treatment of *nocturnal incontinence* of urine by a number of clinicians of repute. (See G. H. M. C., 1889; also *Annals of Gynec.*, 1890.) For elaborate description of the bark, see *Newer Materia Medica*. The adult dose is twenty or thirty minims (1.3–1.8 Cc.) of the fluidextract of the bark, three times a day, given in aromatized solution.

Ricin is the name given by Kobert and Stillmark to the toxic constituent of castor beans. It belongs to the class of albuminoids and is of the character of an enzyme. According to Cushny (A. E. P. P., 1898, 41) ricin is the most active poison known, 0.04 milligramme per kilo of body weight being fatal to the rabbit. The toxic symptoms, which frequently do not come on for several hours after the ingestion of the poison, are due primarily to the intensely irritant action of the substance, and consist of diarrhœa, with suppression of the urine, and frequently jaundice, probably from irritation of the mucous membrane of the biliary ducts. Müller (A. E. P. P., 1899, 42) states that the poison also has a direct action upon the medulla, leading to the fall of blood pressure and lessened respiratory activity.

The effects of ricin in many directions bear a striking resemblance to the effects of bacterial toxins. Thus, for example, it produces a leucocytosis and an agglutination of the red corpuscles. The most interesting, however, of these resemblances is the production of immunity and the formation of antitoxic substances.

Ricinine. $C_{17}H_{12}N_4O_4$.—Tuson first obtained from the seeds of *Ricinus communis*, L., a crystalline substance which he believed to be alka-

loid in nature, and to which he gave the name of *ricinine*. To obtain it, the crushed seeds are exhausted by successive portions of boiling water; the decoction is filtered through wet muslin; the filtered liquor is evaporated to dryness over a water bath; the extract thus obtained is exhausted by boiling alcohol; the alcoholic solution is allowed to cool, then filtered to separate a little resinous matter, and lastly concentrated and permitted to stand. In the course of some hours, a mass of nearly white crystals is deposited, which when recrystallized from alcohol and decolorized by animal charcoal is the alkaloid in a pure state. Ricinine crystallizes in rectangular prisms and tables, melting at 194°C . (381.2°F .), has a feebly bitter taste, somewhat resembling that of bitter almonds, is fusible, and crystallizes on cooling, volatilizing unchanged, inflammable, soluble most readily in water and alcohol, and very slightly in ether or benzene. Heated with potassium hydroxide it evolves ammonia, and therefore contains nitrogen. It appears to combine with sulphuric, nitric, and hydrochloric acids. But a more accurate investigation is needed before it can be admitted to be undoubtedly a distinct and pure alkaloid. A minute quantity is said to be obtained from castor oil by shaking it with water, evaporating the liquid, treating the residue with boiling benzene, and allowing the solution to evaporate spontaneously. Tuson does not claim for the new alkaloid the possession of purgative properties. Two grains (0.13 Gm.) given to a rabbit produced no observable effect. E. E. Wayne obtained from the leaves of *Ricinus communis*, L., a substance which is apparently identical with Tuson's ricinine, but he does not consider it to be an alkaloid. (*A. J. P.*, 1874, p. 97.)

Rimu Resin.—The resin of the *Dacrydium cupressinum*, Solander, the New Zealand red pine or *rimu*, a large coniferous tree of New Zealand, is characterized by its rose color and its crystalline appearance. It is composed chiefly of a crystalline acid resin, *rimuic acid* (*Chem. News*, lxxxviii. 20).

Robinia. *Robinia Pseudacacia*, L. *Locust Tree*. *False Acacia*. *Robinier*, Fr. *Falsche Akacie*, G. (Fam. Leguminosæ).—This well-known indigenous tree has a place in the materia medica of the eclectics. The bark of the root is the most active part, and is said to be tonic, and in large doses purgative and emetic. (For an elaborate investigation of its histology see *P. J.*, 67, 153.) F. B. Power and J. Cambier (*Ph. Rund.*, Feb. 1890) found an alkaloid identical with *choline*; also globulin and phytalbumose, which produces purging and vomiting. It is precipitated by alkaloidal reagents. The bark also contains a poisonous albuminoid or enzyme, *robinabbin*, which, according to Robert (*M. Bull.*, April, 1891), is similar to but not identical with ricin. Power (*P. J.*, Aug. 17, 1901) summarizes the results of a more recent and detailed investigation of this bark. He names the poisonous proteid *robin* and states that it belongs to the class of nucleoproteids. He finds evidences of one or more alkaloids; by hydrolysis he obtained *syringic acid*, $\text{C}_9\text{H}_{10}\text{O}_6$, and a red amorphous substance *syringenin*. These products indicate the glucoside *syringin*, $\text{C}_{17}\text{H}_{24}\text{O}_9$. He also considers that *gluco-syringic acid*, $\text{C}_{15}\text{H}_{20}\text{O}_{10}$, may pre-exist in the bark. Robin has emetic and purgative properties. Three cases of the poisoning of children by the root have been recorded. (*Ann. Ther.*, 1860, 64.) Z. T. Emery (*N. Y. M. J.*, Jan. 22, 1887)

reports the poisoning of thirty-two boys from chewing the inner bark of the tree. The symptoms in the mildest cases were vomiting and flushed face, dryness of the throat and mouth, and dilated pupils. In the severest cases, to these were added epigastric pain, extremely feeble, intermittent heart action, and stupor.

Robinia Nicon.—According to the researches of Geoffroy (*Annal. de l'Inst. botanico-geologique colon. de Marseille*, 1895), this leguminous plant, which is used in Guiana for the purpose of stupefying fish, contains an active principle, *niconline* ($\text{C}_9\text{H}_4\text{O}$), which crystallizes in oblique, rhomboidal tables. It has been found by E. Boinet (*C. R. S. B.*, 1896, 10 s., iii.) to produce in the lower animals a short primary stage of excitation, followed by one of stupor, great muscular relaxation, enfeeblement of sensibility, mydriasis, fall of temperature, cyanosis, and death through centric paralysis of the respiration, though there is also fall of arterial pressure. In the dog there were salivation and vomiting.

Roborin.—This is a dark grayish-green powder, or a dark-brown finely granular mass, said to be obtained from blood, and, according to Lebbin, is composed of water 7.6 per cent., calcium carbonate 10.23 per cent., common salt 1.7 per cent., ferric oxide 0.49 per cent., other mineral substances 1.28 per cent., albuminoids 78.63 per cent. The albuminoids consist principally of calcic albuminates, a small portion of which is soluble in water.

Rosa.—Of the genus *Rosa* at least four species have been, and probably to some extent are still, used in medicine,—namely, *Rosa canina*, L., *Rosa centifolia*, L., *Rosa damascena*, Mill., and *Rosa gallica*, L.

Rosa canina.—The Dog Rose, Wild Brier, or Hip Tree, of Europe, is distinguished by its glabrous ovate ovaries, smooth peduncles, prickly stem and petioles, and ovate, smooth, rigid leaves. It grows from eight to ten feet high, and bears white or pale red flowers, having usually five obcordate fragrant petals. The fruit is fleshy, smooth, oval, red, and of a pleasant, sweet, acidulous taste. It was formerly official in the British Pharmacopœia under the name of *Rosæ Caninæ Fructus*. It contains about 30 per cent. of sugar, combined with citric and malic acids, also salts of these acids, and was used for the preparation of an acidulous confection.

Rosa centifolia has prickly stems, usually from three to six feet high. The leaves consist of two or three pairs of leaflets, with an odd one at the end, closely attached to the common footstalk, which is rough, but without spines. The leaflets are ovate, broad, serrate, pointed, and hairy on the under surface. The flowers are large, with many petals, generally of a pale red color, and supported upon peduncles beset with short bristly hairs. The varieties of *R. centifolia* produced by its almost universal cultivation are very numerous, but the plant is said to grow wild with single flowers in the eastern part of the Caucasus. It is very closely allied to *R. gallica*, some botanists maintaining that the species are really one. The petals, which were recognized by the U. S. P. 1890 as *pale rose*, are roundish-obovate and retuse, or obcordate, pink, fragrant, sweetish, slightly bitter and faintly astringent. They are extremely fragrant, and have a sweetish, slightly acidulous, somewhat bitterish taste. They contain volatile oil, malic and tartaric acids, tanning,

fat, resin, sugar, and a coloring matter which seems to be identical with that of the red rose. They should be collected when the flower is fully expanded but has not begun to fall. Their fragrance is impaired but not lost by drying. They may be preserved for a considerable time by compressing them with alternate layers of common salt in a well-closed vessel, or beating them with twice their weight of that substance. A rose water is often prepared from them by distillation.

Rosa damascena is not known in the wild state, and is thought by some botanists to have been produced by cultivation from *R. gallica*. It is the rose which is cultivated in Turkey and yields the commercial *otto of rose*. (See *Oleum Rosæ*, p. 870.) It is a tall shrub with semi-double, light red to white flowers of moderate size, having several on a branch, though not clustered. Its volatile oil is the basis of rose water.

Rosa gallica is still official (see p. 1067).

Rosemary. *Rosmarinus. Folia Rosmarini, s. Roris Marini. Folia Anthos. Feuilles de Rosmarin, Fr. Cod. Rosmarin, Rosmarinblätter, G. Rosmarino, It. Romero, Sp.*

"The leaves of *Rosmarinus officinalis*, Linné (nat. ord. *Labiatae*)." U. S. 1880. *Rosmarinus officinalis*, Willd., *Sp. Plant.* i. 126; B. & T. 207. Rosemary is an evergreen shrub, three or four feet high, with an erect stem, divided into many long, slender, ash-colored branches. The leaves are numerous, sessile, opposite, more than an inch long, about one-sixth of an inch broad, rigid, linear, entire, obtuse at the summit, folded backward at the edges, of a firm consistence, smooth and green on the upper surface, whitish, woolly, and glandular beneath. The flowers are pale blue or white, and disposed in opposite groups at the axils of the leaves, towards the ends of the branches. The naked seeds are four in number, oblong. The plant grows spontaneously in the countries which border on the Mediterranean, and is cultivated in the gardens of Europe and this country. The leaves, which have already been described, have a strong balsamic odor, which is possessed, but in a less degree, by all parts of the plant. Their taste is bitter and camphorous. These properties are imparted partially to water, completely to alcohol, and depend on the volatile oil. (See *Oleum Rosmarini*, p. 872.) The tops lose a portion of their sensible properties by drying, and become inodorous by age. Rosemary is gently stimulant, and has been considered emmenagogue. In the practice of this country it is scarcely used; but in Europe, especially on the continent, it enters into the composition of several syrups, tinctures, etc., to which it imparts its agreeable odor and excitant property. It is sometimes added to sternutatory powders, and is used externally in connection with other aromatics in the form of fomentation. In some countries it is employed as a condiment; and its flowers, which are much sought after by the bees, impart their peculiar flavor to the honey of the districts in which the plant abounds.

Rotten Stone. *Terra Cariosa*.—An earthy mineral, occurring in light, dull, friable masses, dry to the touch, of a very fine grain, and of an ash-brown color. It is obtained from Derbyshire, in England, and is used for polishing metals. For a particular account of it, see *A. J. P.*, 1860, 463.

Rourea. *Rourea oblongifolia*, Hook. and Arn. (Fam. *Connaraceæ*).—This Mexican creeper is affirmed to contain an alkaloid, and to act as a violent convulsant poison. (*El Estudio*, 1890.)

Rubia. *Garance, Fr. Krappwurzel, Färber-röthe, G. Robbia, It. Rubia de tintoreros, Granza, Sp.*—Under this name the U. S. P. formerly recognized madder, *Rubia tinctorum*, L. (Fam. *Rubiaceæ*.) The root of *dyer's madder* is perennial, and consists of numerous long, succulent fibres, varying in thickness from the size of a quill to that of the little finger, and uniting at top in a common head, from which also proceed side-roots that run near the surface of the ground, and send up many annual stems. These are slender, quadrangular, jointed, procumbent, and furnished with short prickles, by which they adhere to the neighboring plants upon which they climb. The leaves are elliptical, pointed, rough, firm, about three inches long and nearly one inch broad, having rough points on their edges and midrib, and standing at the joints of the stem in whorls of four, five, or six together. The branches rise in pairs from the same joints, and bear small yellow flowers at the summit of each of their subdivisions. The fruit is a round, shining, black berry. The plant is a native of the south of Europe and the Levant, and is cultivated in Asia Minor, France, Holland, and the south of Italy. The root, which is the part used, is dug up in the third summer, and, having been deprived of its cuticle, is dried by artificial heat, and then reduced to a coarse powder. In this condition it is packed in barrels and sent into the market. Madder from the Levant is in the state of the whole root; from the south of France, either whole or in powder. The plant was formerly cultivated in this country, in the States of Delaware and Ohio. The root consists of a reddish-brown bark, and a ligneous portion within. The latter is yellow in the recent state, but becomes red when dried. The powder as found in commerce is reddish brown. Madder has a weak, peculiar odor, and a bitterish, astringent taste, and imparts these properties, as well as a red color, to water and alcohol. It contains as its most important constituent *alizarin*, $C_{14}H_8(OH)_2O_2$, and with it as coloring matter of secondary importance *purpurin*, $C_{14}H_5(OH)_3O_2$. Besides these two technically important constituents there have been recognized *pseudopurpurin*, an orange dye color, and a yellow one (*xanthopurpurin*). These coloring matters, however, are probably decomposition products from glucosides existing in the fresh plant. Thus, alizarin is known to result along with glucose from the treatment with dilute acids of *rubianic* or *ruberythric acid*, $C_{26}H_{28}O_{14}$, according to the reaction:

The most interesting of the coloring substances is the *alizarin*. It may be obtained from the alcoholic extract by sublimation, in the method employed by Mohr in obtaining benzoic acid. (See *J. P. C.*, 3e sér., xxxi. 267.) It is orange-red, inodorous, insipid, crystallizable, capable of being sublimed without change, scarcely soluble in cold water, soluble in boiling water, and very readily so in alcohol, ether, the fixed oils, and alkaline solutions. The alcoholic and aqueous solutions are rose-colored; the ethereal, golden yellow; the alkaline, violet and blue when concentrated, but violet-red when sufficiently diluted. A beautiful rose-colored lake is produced by precipitating a mixture of the solutions of alizarin and alum. Alizarin was recognized by Graebe and Liebermann in 1868 as a derivative of anthracene, $C_{14}H_{10}$ —a hydrocarbon contained in coal tar—and in the same year they elaborated a method

for preparing it commercially from anthracene. Upon this arose rapidly a great chemical industry, so that in 1881 the amount of artificial alizarin annually produced was 14,000 tons of 10 per cent. paste, valued at \$8,000,000. The production of madder, of course, decreased correspondingly. The exportations of madder from France, which in 1872 had a value of \$1,850,000, decreased to \$70,000 in 1878, and \$53,000 in 1883. The importations of alizarin into the United States for the following years have been: for 1903, 4,448,886 lbs., and for 1904, 4,456,145 lbs. Madder also contains sugar; and Döbereiner succeeded in obtaining alcohol from it by fermentation and distillation, without affecting its coloring properties.

Madder is used in *amenorrhœa* and *dropsy*, and when taken into the stomach imparts a red color to the milk and urine, and to the bones of animals, without sensibly affecting any other tissue. The effect is observable most quickly in the bones of young animals, and in those nearest the heart. Under the impression that it might effect some change in the osseous system, it has been prescribed in *rhachitis*, but without favorable result. Dose, about half a drachm (2.0 Gm.), repeated three or four times a day.

Rubidium.—Salts of rubidium may be obtained much more cheaply than in former years, on account of Erdmann's process for the recovery of these salts from the Stassfurt potash deposits. Two salts have been brought forward for use in practical medicine.

• *Rubidium iodide*, RbI, which occurs in whitish crystals, freely soluble in water, has been recommended by Harnack, Neisser, and others as a substitute for potassium iodide, than which it is asserted to be better borne by the stomach. The dose is that of potassium iodide. G. Jacotini affirms that rubidium iodide is a specific in *coryza*.

Rubidium ammonium bromide, RbBr.3NH₄Br. The double ammonium and rubidium bromide is affirmed by Laufenaue to be the most active of all the bromides in the treatment of *epilepsy*. It is given in doses of sixty to eighty grains (3.9-5.2 Gm.) once a day.

Rubidium bromide, RbBr, may be used as a substitute for, and in the dose of, potassium bromide, than which it is said to be better borne, especially by feeble patients.

Rubus. *Rubus Chamemorus*, L. *Cloud Berry*. (Fam. Rosaceæ.)—This plant, which inhabits the northern portions of both continents, is largely employed in Northern Russia, in the form of an infusion of the berries or leaves, as a diuretic in *dropsy*. Popoff found in it a crystallizable acid which is an essential diuretic, acting directly upon the renal secreting structures without affecting either cardiac action or arterial tension. (Vrach, iv. 1886.)

The U. S. Pharmacopœia formerly recognized under the name of *Rubus idæus*, or *raspberry*, the fruit of the ordinary cultivated raspberry, *Rubus idæus*, L., to which plant *Rubus strigosus*, Michaux, or the wild red raspberry of the Northern United States, is so closely allied as by some botanists to be considered as simply a variety. *Rubus strigosus* has also yielded to cultivation certain superior raspberries, especially those which have been known commercially as the Cuthbert and Hansall raspberries. *Rubus neglectus*, Peck, the purple wild raspberry, with a fruit which varies from dark red or purple to yellowish in cultivation, has also yielded a commercial raspberry.

The fruit of these raspberries may be employed for the production of raspberry syrup (*Syrupus Rubi Idæi*, U. S. 1890). For the making of this syrup the former directions of the U. S. Pharmacopœia were sufficient. They are as follows: "Fresh, Ripe Raspberries, any convenient quantity; Sugar, a sufficient quantity. Reduce the Raspberries to a pulp, and let this stand, at a temperature of about 20° C. (68° F.), until a small portion of the filtered juice mixes clear with half its volume of alcohol. Then separate the juice by pressing, set it aside, in a cool place, until the liquid portion has become clear, and filter. To every forty parts by weight of the filtrate (which should not be allowed to remain, unprotected by sugar, more than about two hours) add sixty parts of Sugar, heat the mixture to boiling, avoiding the use of tinned vessels, and strain. Keep the product in well-stoppered bottles, in a cool and dark place." The U. S. P. of 1890, for the purpose of detecting aniline, which is not rarely added to raspberry syrup to give it color and conceal lack of strength, required that on shaking separate portions of the syrup with ether, chloroform, or amyl alcohol, no color should be imparted to the liquid used. The primary fermentation of raspberry juice frees it from albuminous and pectinous substances, which interfere with the transparency of the syrup, and, if not separated, would seriously increase the risk of its spoiling. The flavor of the juice is not injured, although the process must be carefully watched to keep the fermentation from passing from the vinous to the acetous.

The *Rubus occidentalis*, L., black raspberry or thimbleberry of the Northern United States, which is also cultivated, is sometimes employed for the making of a raspberry syrup, but yields a very inferior product.

Rumex. U. S. 1890. *Rumex. Yellow Dock*. Several species of *Rumex* have sour leaves, and are distinguished by the common name of *sorrel* from the others, which are called *dock*. Of the former, *Rumex Acetosella*, L., or common *English sorrel*, formerly held a place in the London and Dublin Pharmacopœias. *R. Acetosella*, L., is the common sorrel of our fields, though supposed to have been originally introduced from Europe. The leaves of both these plants are agreeably sour to the taste, and owe their acidity to acid potassium oxalate with a little tartaric acid. They quite lose this taste in drying. They are refrigerant and diuretic, and may be used advantageously as an article of diet in scurvy. For this purpose they are prepared in the form of salad. The juice of the leaves forms with water an agreeable acidulous drink, sometimes used in fevers. Taken very largely, the leaves are said to have produced poisonous effects. (See Wood's *Quarterly Retrospect*, i. 109.) *R. scutatus*, L., of Europe, Northern Africa, Asia Minor, and the Caucasus, also ranks among the sorrels (*French sorrel*).

Of the proper docks, the roots of *R. Patentia*, L., and *R. alpinus*, L., European plants, and of *R. aquaticus*, *R. acutus*, and *R. sanguineus*, L., belonging both to Europe and to the United States, may be employed indiscriminately with those of the *R. crispus*, L., which was formerly recognized by the U. S. Pharmacopœia. *R. britannicus*, L., and *R. obtusifolius*, L., were formerly official. *R. Hydrolapathum*, Hudson, which is the *R. aquaticus* of the old Dublin Pharmacopœia, is thought to be the *Herba Britannica* of the ancients, celebrated for the cure of scurvy and diseases of the

skin. The docks are herbaceous plants with perennial roots. The flowers are in terminal or axillary panicles. Some of the species are dioecious; but the *R. crispus* has perfect flowers.

Dock root, from whatever species derived, has an astringent, bitter taste, with little or no odor. It readily yields its virtues to water by decoction. The root of *R. crispus* was officially described as "from 20 to 30 Cm. long, about 10 to 15 Mm. thick, somewhat fusiform, fleshy, nearly simple, annulate above, deeply wrinkled below; externally rusty brown, internally whitish, with fine, straight, interrupted, reddish medullary rays, and a rather thick bark; fracture short; odor slight, peculiar; taste bitter and astringent." *U. S.* 1890. According to Riegel, the root of *R. obtusifolius* contains resin, extractive matter resembling tannin, starch, mucilage, albumen, lignin, sulphur, and various salts, among which are calcium phosphate and different acetates and malates. (*J. P. C.*, 3e sér., i. 410.) The leaves of most of the species are edible when young, and are occasionally used as spinach. They are somewhat laxative, and form an excellent diet in scorbutic cases. The roots are used to dye a yellow color. According to J. H. Salisbury (*N. Y. Journ. Med.*, March, 1855), the petioles of the leaves contain nearly one per cent. of oxalic acid; the cortical part of the root, which is the most active, yielded, on analysis, starch, a little sugar, albuminous matter, gummy matter, bitter extractive, tannic acid of the kind which gives green precipitates with the salts of iron, lignin, and various salts. The root yields its virtues to water and to alcohol, but is injured by long boiling. Dock root is astringent, gently tonic, and has been supposed to have alterative properties, making it useful in skin diseases and even syphilis. From the root of *R. nepalensis*, Wall., which is largely used in Madras as an astringent for medicinal purposes and for dyeing, O. Hesse has separated three crystalline substances to which he gives the names of *rumicin*, *nepalin*, and *nepodin*. (*P. J.*, lvi.; also *Proc. A. Ph. A.*, 1896, 551.) *R. aquaticus* and *R. britannicus* are the most astringent. The roots of some species unite a laxative with the tonic and astringent property, resembling rhubarb somewhat in their operation. Such are those of *R. crispus* and *R. obtusifolius*; and *R. alpinus*, L., has in some parts of Europe the name of *mountain rhubarb*. This resemblance is not singular, as the two genera belong to the same natural family. Dock root is given in powder or in decoction. Two ounces (62 Gm.) of the fresh root bruised, or one ounce (31 Gm.) of the dried, may be boiled in a pint (480 Cc.) of water, of which two fluid-ounces (60 Cc.) may be given at a dose, and repeated as the stomach will bear it. George G. Fleming (*L. L.*, i. 1896) reported the death of two sisters, aged respectively five and six and a half years, preceded by symptoms of oxalic acid poisoning as the result of the ingestion of sorrel leaves.

Fluidextract of Rumex (Fluidextract of Yellow Dock).—"Rumex, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains]; Diluted Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with three hundred and fifty cubic centimeters [or 11 fluidounces, 400 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid

begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until the Rumex is exhausted. Reserve the first eight hundred cubic centimeters [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the fluidextract measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]." *U. S.* 1890. The dose is a fluidrachm (3.75 Cc.).

Ruta.—Under this name the *U. S. Pharmacopœia* formerly recognized *Ruta graveolens*, L.; *Common rue*; *Rue odorante*, Fr.; *Garten-Raute*, G.; *Ruta*, It.; *Ruda*, Sp. (Fam. Rutaceæ.) It is a perennial plant usually two or three feet high, with several shrubby branching stems, which, near the base, are woody and covered with a rough bark, but in their ultimate ramifications are smooth, green, and herbaceous. The leaves are doubly pinnate, glaucous, with obovate, sessile, obscurely crenate, somewhat thick and fleshy leaflets. The flowers are yellow, and disposed in a terminal branched corymb upon subdividing peduncles. The calyx is persistent, with four or five acute segments; the corolla consists of four or five concave petals, somewhat sinuate at the margin. There are usually ten stamens, but sometimes only eight. The plant is a native of the south of Europe, but cultivated in our gardens. It flowers from June to September. The whole herb is active, and yields its properties to water and alcohol. The leaves have a strong disagreeable odor, especially when rubbed. Their taste is bitter, hot, and acrid. When recent, and in full vigor, they have so much acrimony as to inflame and even blister the skin, if much handled; but the acrimony is diminished by drying. Their virtues depend chiefly on a volatile oil, which is contained in glandular vesicles, apparent over the whole surface of the plant. They contain, also, according to Mähl, chlorophyll, albumen, a nitrogenous substance, extractive, gum, starch or inulin, malic acid, lignin, and, according to Bornträger, a peculiar acid which he calls *rutinic acid*, $C_{25}H_{28}O_{15}$ (or $C_{27}H_{32}O_{16}$, according to later writers). Rutinic acid is the coloring principle of rue, and has been found in various other plants; though, like quercitrin, yielding quercetin and sugar, it has been shown to be distinct. (*J. P. C.*, 1862, 165.)

Rue yields a very small proportion of a yellow or greenish volatile oil, which becomes brown with age. According to Zeller, the product from the fresh herb is 0.28 per cent., that from the seeds about 1 per cent. The oil has the strong unpleasant odor of the plant, and an acrid taste. Kane gives its sp. gr. at 0.837, its boiling point at 230° C. (446° F.). "A neutral reaction. Sp. gr. about 0.880. It is soluble in an equal weight of alcohol." *U. S.* 1880. It consists mainly of an oxidized constituent, which Strecker proved to be methyl-nonyl-ketone, $CH_3.CO.C_9H_{19}$; that is, a ketone analogous to acetone, $CH_3.CO.CH_3$. This accounts for its yielding under treatment with oxidizing agents, pelargonic acid, $C_9H_{18}O_2$. The methyl-nonyl-ketone, when pure, is a colorless liquid, fluorescing blue, boiling at 225° C. (437° F.), and crystallizing at about 15° C. (59° F.). When treated with nitric acid it yields, among other products, pelargonic acid. Schimmel & Co. (*Schim. Rep.*, 1892, 31) state that pure oil of

rue consists of 90 per cent. of methyl-nonyl-ketone, and solidifies even at a moderate temperature to a solid, crystalline mass, and has the sp. gr. 0.837.

According to von Soden and Henle, *Algerian oil of rue* differs from the ordinary oil in that it is chiefly composed of methyl-heptyl-ketone, with but small quantities of methyl-nonyl-ketone. Its specific gravity at 15° C. (59° F.) is 0.842; and it does not solidify at -15° C. (5° F.). (*Ph. Ztg.*, 46.) Frederick B. Power and Frederic H. Lees (*Trans. Chem. Soc.*, 1902) have since published an elaborate investigation of a similar Algerian oil. They find 80 per cent. of the two ketones, methyl-heptyl-ketone and methyl-nonyl-ketone, 10 per cent. of the corresponding carbinols (alcohols), pinene, l-limonene, cineol, methyl salicylate, ethyl valerate, and some free fatty acids.

Rue is said to have been used by the ancients as a condiment. In modern times it has been employed in *hysteria*, *worms*, *colic*, and atonic *amenorrhœa* and *menorrhagia*. Its medicinal activity depends upon its volatile oil, which is a powerful local irritant, causing, when applied to the skin persistently, burning, redness, and vesication, and when taken internally in large doses, violent gastric pains and vomiting, great prostration, confusion of mind, convulsive twitching, and in pregnant women, abortion. It has been considerably used in Europe for the production of criminal abortion, in a number of cases with fatal results. In a case of fatal poisoning in a man, reported by G. F. Cooper, there were vomiting, violent tormina and tenesmus, with bloody stools, great abdominal distention, with tenderness and severe strangury. (*Med. Exam.*, N. S., ix, 720.) The dose of the oil is from two to five minims (0.12-0.3 Cc.) every two or three hours. The rue itself is sometimes given in the dose of from ten to thirty grains (0.65-2.0 Gm.).

Rye. *Secale cereale*, L. (Fam. Gramineæ.) Syria, Armenia, and the southern provinces of Russia have been severally indicated as the native country of rye. The plant is now cultivated in all temperate latitudes. The grains consist, according to Einhof, of 24.2 per cent. of envelope, 65.6 of flour, and 10.2 of water. The average composition of rye as a cereal may be thus stated: fat, 1.43 per cent.; starch, 61.87 per cent.; sugar (as sucrose), 4.30 per cent.; albumen (insoluble in alcohol), 9.78 per cent.; nitrogenous matter (soluble in alcohol), 5.09 per cent.; cellulose, 3.23 per cent.; mineral matter, 1.85 per cent.; moisture, 12.45 per cent. (Sadler, *Industrial Organic Chemistry*, 3d ed., p. 169.) Rye flour is much used, in the dry state, as an external application to *erysipelatosus inflammation* and other eruptive affections, the burning and unpleasant tingling of which it tends to allay, while it absorbs the irritating secretions. In the form of mush it is an excellent laxative article of diet, and, mixed with molasses, it may be given with great advantage in *hemorrhoids* and *prolapsus ani*, connected with *constipation*. Rye carbonized by heat, with exclusion of the air, has been highly recommended as a tooth powder.

Sabadilla. *Cevadilla*.—The dried ripe seeds of *Asagraea officinalis* (Cham. and Schlecht.), Lindl. (*Schœnocaulon officinale*, A. Gray), were recognized by the Br. Pharm. of 1885. At one time cevadilla was generally believed to be derived from *Veratrum Sabadilla*, Retz. Schiede, during his travels in Mexico, ascertained that it was, in part at least, collected from a different plant, of the

same family (Liliaceæ), growing upon the eastern declivity of the Mexican Andes. This was considered by Schlechtendal as another species of *Veratrum*, by Don as a *Helonias*, and by Lindley as belonging to a new genus which he named *Asagraea*. Hence it has been variously denominated *Veratrum officinale*, Schlecht. and Cham., *Helonias officinalis*, D. Don, *Asagraea officinalis*, Lindl., and *Schœnocaulon officinale*, A. Gray. It is not probable that *Veratrum Sabadilla*, Retz, yields much, if any, of the seed of commerce; but it would seem that very much of the drug is the product of a plant so different from *Asagraea officinalis* that Ernst of Caracas believes it to be a new species. It differs chiefly in having its leaves broader and more carinate.

Cevadilla seeds usually occur in commerce mixed with the fruit. This consists of three coalescing capsules or follicles, which open above and appear like a single capsule with three cells. It is three or four lines long and a line and a half in thickness, obtuse at the base, light brown or yellowish, smooth; each of the component capsules contains one or two seeds. A resemblance, existing or supposed, between this fruit and that of barley is said to have given rise to the Spanish name cevadilla, which is a diminutive of barley. The seeds are elongated, pointed at each end, flat on one side and convex on the other, somewhat curved, two or three lines long, wrinkled, slightly winged, black or dark brown on the outside, whitish within, hard, inodorous, and of an exceedingly acid, burning, and durable taste.

Pelletier and Caventou first noted the presence of an alkaloid in cevadilla, which base they called *veratrine*; Meissner in the same year announced the presence of an alkaloid, *sabadilline*, and Couërbe, Merck, and Weigelin all described what they considered as distinct bases; but its exact composition remained unsettled until Wright and Luff (*J. Chem. S.*, 33, 338) found in it three bases: 1. *cevadine*, $C_{32}H_{49}NO_9$ (agreeing with the base described by Merck as *veratrine*), crystallizing in needles or compact crystals, fusing at 205° C. (401° F.) (202° C. (395.6° F.)), according to Merck), insoluble in water, easily soluble in alcohol and ether, and decomposed by hot alcoholic potash into *cevine*, $C_{27}H_{43}NO_8$ ($C_{27}H_{45}NO_8$, Flückiger), and *methyl-crotonic acid* (*cevadio acid* of Pelletier and Caventou), $C_5H_9O_2$; 2. *veratrine*, $C_{37}H_{53}NO_{11}$, obtained from the syrupy mother liquor from which the cevadine has crystallized; it is uncrystallizable, soluble in ether, and decomposed by alcoholic soda into *verine*, $C_{28}H_{45}NO_8$, and dimethyl-protocatechuic acid (*veratric acid* of Merck), $C_7H_4(CH_3)_2O_4$; 3. *cevadilline*, $C_{34}H_{53}NO_8$, obtained after the extraction of the veratrine with ether; it is insoluble in ether, slightly soluble in boiling benzene, and readily soluble in fusel oil, uncrystallizable, and appears to yield methyl-crotonic acid on treatment with alcoholic soda.

The second of these alkaloids, *veratrine*, Flückiger (*Pharm. Chem.*, 2d ed., 1888, 531) considers as isomeric with cevadine, $C_{32}H_{49}NO_9$, and writes the reaction for its decomposition,

Wright and Luff extract the alkaloids as follows. One hundred parts of sabadilla seeds are exhausted with one part of tartaric acid and alcohol, the alcoholic extract concentrated, freed

from resinous admixture by addition of water, and then treated with sodium hydroxide and ether. The ethereal solution is then shaken up with aqueous tartaric acid solution, and the acid liquid again treated with sodium hydroxide and ether. The ethereal solution is now mixed with ligroin (light petroleum benzin), and allowed to evaporate spontaneously. A syrupy liquid separates out first, and then crystals of cevadine, which are drained off and recrystallized from alcohol. The residual syrupy liquid consists essentially of veratrine and cevadilline. Ten kilogrammes (24 pounds) of seeds yield from sixty to seventy grains of alkaloids, from which eight to nine grains of pure cevadine, five to six grains of veratrine, and two to three grains of crude cevadilline can be isolated.

Merck has since (*M. R.*, Jan. 1891, 3-9) isolated two new alkaloids from cevadilla, which he names *sabadine* and *sabadinine* respectively. The former has the formula $C_{29}H_{51}NO_8$, crystallizes from ether in short needles, and fuses at from 238° to 249° C. (460.4°-464° F.). It dissolves in concentrated sulphuric acid with a yellow color and a green fluorescence, which gradually disappears, while the liquid assumes a blood-red and then violet color. The alkaloid is sternutatory, although in a much less degree than veratrine. The second alkaloid crystallizes from ether in filiform needles, which begin to sinter at 160° C. (320° F.), but show no fixed fusing point. Concentrated sulphuric acid causes a permanent blood-red color. The formula is given as $C_{27}H_{45}NO_8$. The alkaloid is not sternutatory. Cevadilla yields about 0.3 per cent. of veratrine. (See *Veratrina*, p. 1327.)

Cevadilla is an acrid, drastic emeto-cathartic, operating occasionally with great violence, and in overdoses capable of producing fatal effects. Known in Europe as early as 1752, and formerly used to some extent as a tannicide, in doses of from five to twenty grains (0.32-1.3 Gm.), it was official solely as the source of veratrine. It is the principal ingredient of the *pulvis Capucinum*, sometimes used in Europe for the destruction of vermin in the hair.

According to E. Falk, 0.001 Gm. of pure cevadine will paralyze the frog; 0.01 Gm. will cause death from cardiac paralysis in rabbits; 0.02 Gm. per kilogramme produces paralysis, interrupted by tetanic spasms. Cevine was found to be much less poisonous than cevadine, though producing similar symptoms.

Sabbatia. *Centaurée Américaine*, Fr. *Sabbatie*, G.—Of this gentianaceous genus three American species are more or less used in popular medicine as tonics and as antiperiodics. They are, in fact, simple bitters of some activity, and may very well be substituted for the foreign remedies of their class. Their value in intermittent fever is probably simply that of quassia and gentian, only somewhat more feeble. The *S. angularis* (L.), Pursh, or *American centauray*, was formerly recognized by the U. S. Pharmacopœia in its Secondary List. A description of it may be found in the 16th edition of the *U. S. D.* John F. Hunecker found in it a small proportion of *erythrocentaurin*, $C_{27}H_{45}O_8$, previously discovered by Méhu, a French chemist, in *Erythrœa Centaurium*, Pers., of Europe. Hunecker also obtained, from *American centauray*, resin, chlorophyll, fatty matter, gum, albumen, pectin, bitter extractive, traces of volatile oil, an organic acid, red coloring matter, and salts. (*A. J. P.*, 1871, 207.)

In the Southeastern United States, the *Sabbatia Elliottii*, Steud., or *Quinine flower*, and in the Southwestern United States the *Sabbatia campestris*, Nutt., have been employed like the *S. angularis* in the North. They probably contain the same active principle. Of the *S. angularis* and the *S. campestris* the whole plant is used, the dose being a drachm (3.9 Gm.), given in the form of fluidextract or in decoction. Of the Quinine flower, the root is employed; dose of the fluidextract, one fluidrachm (3.75 Cc.); in intermittent fever to be repeated at short intervals.

Sagapenum.—This gum-resin, formerly highly esteemed, but at present very rarely met with even in Eastern commerce, is the concrete juice of an unknown Persian plant, supposed by some to be one of the species of *Ferula* (Fam. Umbelliferae) related to those that yield galbanum. It is in irregular masses, composed of agglutinated fragments, slightly translucent, of a brownish-yellow, olive, or reddish-yellow color externally, paler internally, brittle, of a consistence somewhat resembling that of wax, and often mixed with impurities, especially with seeds more or less entire. An inferior variety is soft, tough, and of uniform consistence. It has an alliaceous odor less disagreeable than that of asafetida, and a hot, nauseous, bitterish taste. It softens and becomes tenacious by the heat of the hand. The effect of time and exposure is to harden and render it darker. It is inflammable, burning with a white flame and much smoke, and leaving a light spongy charcoal. Pure alcohol and water dissolve it partially, diluted alcohol almost entirely. Distilled with water it affords a small quantity of volatile oil, and the water is strongly impregnated with its flavor. According to Tschirch (*Harze und Harzbehälter*, 229), it contains 23.3 per cent. of gum; 19.2 per cent. of essential oil, containing sulphur; and 57.5 per cent. of a resin which is free from sulphur and melts at 74° to 76° C. (165.2°-168.8° F.). The ether soluble resin of sagapenum can be separated by saponification into *umbelliferone* and *sagaresitannol*, $C_{24}H_{27}O_4$. This latter yields on oxidation *oxyopicric acid*. The oil is pale yellow, very fluid, lighter than water, and of a disagreeable alliaceous odor. Sagapenum was considered by the older physicians as midway in its medicinal properties between asafetida and galbanum, and was used in doses of from ten to thirty grains (0.65-2.0 Gm.) in *amenorrhœa*, *hysteria*, etc.; also externally in plasters as a discutient.

Sago. *Sagu*, Fr. *Sago*, G., It. *Sagu*, Sp. Under this name the U. S. P. formerly recognized the starch obtained from the sago palms. Numerous trees, inhabiting the islands and coasts of the Indian Ocean, contain a farinaceous pith, which is applied to the purposes of nutriment by the natives. Such are *Metroxylon Sagu*, Rottb. (*Sagus laevis*, Blume), *Metroxylon Rumphii* (Willd.), Mart. (*Sagus Rumphii*, Willd.), *Raphia pedunculata*, Beauv. (*Sagus ruffia*, Jacq.), *Arenca saccharifera*, Labill. (*Saguerus Rumphii*, Roxb.), and *Phœnia farinifera*, Roxb., belonging to the family of Palms, and *Cycas circinalis*, L., *Cycas revoluta*, Thunb., and *Zamia lanuginosa*, belonging to the Cycadaceæ. The fruit of the *Cycas circinalis*, according to J. van Donjen, contains a poisonous glucoside, *pakōïne* (P. J., May, 1903); and it is doubtful if any other trees than *Metroxylon Sagu*, *M. Rumphii* and *Arenca saccharifera* contribute to furnish the sago of commerce. Crawford, in his *History of the Indian Archipelago*,

states that it is derived exclusively from *Metroxylon Sagu*, Rottb., but Roxburgh ascribes the granulated sago to *S. laevis*, Jack (which subsequent research shows to be *Metroxylon Sagu*, Rottb.); and one of the finest kinds is said by Hamilton to be produced by *Arenga saccharifera*, Labill. The farinaceous product of the different species of *Cycas*, sometimes called *Japan Sago*, does not enter into general commerce.

Metroxylon Rumphii (Willd., *Sp. Pl.* iv. 404), Mart.; Carson, *Illust. of Med. Bot.*, ii. 44, pl. 88. *Metroxylon Sagu*, Rottb. (1783); *Bentley and Trimen*, 278.—The sago palm is one of the smallest trees of its family. Its height seldom exceeds thirty feet. The trunk is proportionately very thick, quite erect, cylindrical, covered with the remains of the old leafstalks, and surrounded by a beautiful crown of foliage, consisting of numerous, very large, pinnate leaves, extending in all directions from the summit, and curving gracefully downward. The fruit is a roundish nut, covered with an imbricated coat, and containing a single seed.

The tree is a native of the East India islands, growing in the Peninsula of Malacca, Sumatra, Borneo, Celebes, the Moluccas, and a part of New Guinea. It flourishes best in low and moist situations. Before attaining maturity, the stem consists of a shell, usually about two inches thick, filled with an enormous volume of spongy medullary matter like that of elder. This is gradually absorbed after the appearance of fruit, and the stem ultimately becomes hollow. The greatest age of the tree is not more than thirty years. Large quantities of a kind of sugar called *jaggary* are produced from its juice. According to H. von Rosenberg (*Proc. A. Ph. A.*, xxvii. 140), the medullary matter consists mostly of starch when the large leaves have fallen off and the flowers are just taking their place. At this time the tree is felled, and the trunk cut into billets six or seven feet long, which are split in order to facilitate the extraction of the pith. This is obtained in the state of a coarse powder, which is mixed with water in a trough having a sieve at the end. The water, loaded with farina, passes through the sieve, and is received in convenient vessels, where it is allowed to stand till the insoluble matter has subsided. It is then strained off, and the farina which is left may be dried into a kind of meal or moulded into whatever shape may be desired. For the consumption of the natives it is usually formed into cakes of various sizes, which are dried, and extensively sold in the islands. The commercial sago is prepared by forming the meal into a paste with water, and rubbing it into grains. It is produced in the greatest abundance in the Moluccas, but of the finest quality on the eastern coast of Sumatra. The Chinese of Malacca refine it so as to give the grains a fine pearly lustre. Malcolm states that it is also refined in large quantities at Singapore. In this state it is called *pearl sago*, and is in great repute. It is said that five or six hundred pounds of sago are procured from a single tree.

Pearl sago is that which is now generally used. It is in small grains, about the size of a pin head, hard, whitish, of a light brown color, in some instances translucent, inodorous, and with little taste. It may be rendered perfectly white by a solution of chlorinated lime. *Common sago* is in larger and browner grains, of more unequal size, of a duller aspect, and frequently mixed with more or less of a dirty looking powder.

Sago meal is imported into England from the East Indies. It is in the form of a fine amylaceous powder, of a whitish color, with a yellowish or reddish tint, and of somewhat musty odor.

Common sago is insoluble in cold water, but by long boiling unites with that liquid, becoming at first soft and transparent, and ultimately forming a gelatinous solution. Pearl sago is partially dissolved by cold water, probably owing to the heat used in its preparation. Chemically considered, it is a very pure natural starch, as the nitrogenous matter rarely amounts to more than one per cent., and the ash to one-half per cent., the remainder being starch and moisture. Under the microscope the granules of sago meal appear oval or ovate, and often truncated so as to be more or less muller-shaped. Many of them are broken, and in most the surface is irregular or tuberculated. They exhibit upon their surface concentric rings, which are much less distinct than in potato starch. The hilum is circular when perfect, and cracks either with a single slit or a cross, or in a stellate manner. The granules of pearl sago are of the same form, but are all ruptured, and exhibit only indistinct traces of the annular lines, having been altered in the process employed in preparing them. Those of common sago are very similar to the particles of sago meal, except that they are perhaps rather less regular and more broken.

Potato starch is sometimes prepared so as to resemble bleached pearl sago, for which it is sold. But, when examined under the microscope, it exhibits larger granules, which are also more regularly oval or ovate, smoother, less broken, and more distinctly marked with the annular rugæ than are those of sago, and the hilum often cracks with two slightly diverging slits. Sago is now made in the United States from various kinds of starch.

Sago is used exclusively as an easily digestible, non-irritating food. It is given in the liquid state, and in its preparation care should be taken to boil it long in water, and stir it diligently, in order that the grains may be thoroughly dissolved. Should any portion remain undissolved, it should be separated by straining. A tablespoonful to the pint of water is usually sufficient.

Salacetol. *Salicyl-acetol.* *Salantol.* $C_6H_4(OH)CO.OCH_2CO.CH_3$.—A synthetic product, the ester of salicylic acid and acetylcarbinol, introduced as a substitute for salol, to avoid the elimination of phenol in the system. Crystallizes out of alcohol in needles, fusing at $71^\circ C.$ ($159.8^\circ F.$), slightly soluble in cold water and alcohol, readily soluble in ether, chloroform, and petroleum benzin. It may be used when salol is indicated, in doses of from thirty to forty-five grains (2.0–3.0 Gm.).

Salacetol.—A mixture of the sodium salts of salicylic and lactic acids, said to contain 71.1 per cent. of salicylic acid. A one per cent. solution of salacetol in solution of hydrogen dioxide has been used to arrest the growth of diphtheritic membrane.

Salamander Alkaloids.—*Salamander maculosa*, and probably other newts, produce a poisonous secretion from the skin, from which Hoppe-Seyler and Zalesky separated an active body, *salamandarine*. E. S. Faust (*A. E. P. P.*, xliii.) has secured crystalline salts from this body which produce in the lower animals restlessness, excited reflex activity, and convulsions ending in total paralysis. A second alkaloid, *salamandaridine*, was also separated by Faust.

Salep. *Tubera Salep*, P. G. *Salep*, Fr., G. This name is given to the dried tubers of numerous species of the genus *Orchis*, and in India of the genus *Eulophia*. At present the salep of European commerce is prepared chiefly in the Levant, but to some extent in Germany and other parts of Europe. The German salep is said to be more translucent than the Levant.

Salep is in small, oval, irregular, ovoid or oblong tubers, rarely palmate, hard, horny, semi-transparent, of a yellowish color, a feeble odor, and a mild mucilaginous taste. It is sometimes kept in the state of powder. In composition and relation to water it is closely analogous to tragacanth, consisting of a substance insoluble but swelling up in cold water (*bassorin*), of another in much smaller proportion, soluble in cold water, and of minute quantities of saline matters. It also occasionally contains a little starch. It is highly nutritive, and may be employed for the same purposes as tapioca, sago, etc. Its mediæval and Oriental reputation as an aphrodisiac is unfounded. On account of its hardness, salep, in its ordinary state, is of difficult pulverization; but the difficulty is removed by macerating it in cold water until it becomes soft, and then rapidly drying it. *Royal salep*, said to be much used as a food in Afghanistan, has been identified by J. E. T. Aitchison as the product of *Allium Macleanii*, Baker. (Fam. Liliaceæ.) (P. J., Sept. 1889.)

Salihypnone. $C_6H_4O(COC_6H_5)COOCH_3$.—A benzoyl-methyl-salicylic ester which occurs in colorless needles melting at 113° C. (235.4° F.), insoluble in water and sparingly soluble in alcohol and ether. It is a mild antiseptic.

Salicylamide. $C_6H_4 \begin{Bmatrix} OH \\ CONH_2 \end{Bmatrix}$. This compound is prepared by the action of concentrated ammonia upon methyl salicylate. When purified, it occurs in perfectly colorless, thin, transparent plates, melting at 138° C. (280.4° F.), soluble in alcohol, ether, chloroform, and two hundred parts of water. W. B. Nesbitt finds that this substance, when given in toxic dose, paralyzes the motor nerves and centres, also the muscles, and has but little effect upon blood pressure. He believes that it is a safer remedy than salicylic acid, and has the advantage of greater solubility and more prompt action in smaller dose. Also, that it has analgesic and antipyretic properties which correspond. It may be given in doses of three grains (0.2 Gm.). The highest amount used was fifteen grains (1.0 Gm.), taken in nine hours. (T. G., Oct. 1891.)

Salicylbromanilide. *Antinervine*.—This was first described as a mixture of bromacetanilide and salicylanilide, but a specimen analyzed by Ritsert was shown to be a mixture of ammonium bromide, salicylic acid, and acetanilide. Salicylbromanilide has been asserted to be a safe antipyretic and antineuralgic by Radlauer of Germany, but C. S. Bradfute (*New England Monthly*, April, 1891) has found it to be a violent depressant of the heart. In *angina pectoris*, with high tension, he obtained relief by its use, but it seems to be a dangerous remedy. Dose, from five to ten grains (0.32–0.65 Gm.).

Salifebrin. *Salicylanilide*.—An antipyretic, made by heating together salicylic acid and acetanilide in molecular proportions. It is a colorless permanent powder, insoluble in water, freely soluble in alcohol.

Saliformin. *Formin Salicylate*. *Hexamethylene-tetramin-salicylate*. *Urotropin Salicylate*.

$(CH_2)_6N_4.C_6H_4(OH)COOH$.—A colorless, crystalline powder, having an acidulous taste, soluble in water and alcohol, used as an antiseptic and for its supposed solvent powers on uric acid deposits. The daily dose is from fifteen to thirty grains (1.0–2.0 Gm.).

Saligallol. *Pyrogallol Di-salicylate*.—A resinous solid, soluble in two parts of acetone and fifteen parts of chloroform. Its solution in acetone has been used as an external application in skin diseases.

Saligenin. *Ortho-oxybenzyl alcohol*, $C_6H_4.OH.CH_2OH$, is the decomposition product of the glucoside *salicin*. Under the name of *antiarthrin*, a substance has been introduced into commerce which is said to be a combination product between saligenin and tannin. It readily undergoes decomposition. It has been used in chronic *rheumatism* and *gout* in doses of ninety to one hundred and fifty grains (5.8–9.8 Gm.) a day.

Saliphen. *Saliphenin*. *Salicyl-p-phenetidin*. $C_6H_4(C_2H_5)NH.C_6H_4(OH)CO$.—This substance is the product of a reaction between salicylic acid and phenetidin in the presence of phosphorus trichloride. It is in colorless crystals, which melt at 139.5° C. (283° F.); is insoluble in water but soluble in boiling alcohol, acetone, ether, chloroform and glacial acetic acid. It possesses slight antifibrile properties.

Salipyrin. *Antipyrine Salicylate*. *Salazolon*. $C_{11}H_{12}N_2O.C_7H_5O_3$.—Prepared by the action of salicylic acid upon antipyrine, either at 100° C. (212° F.) or in solution. It occurs as a white, coarsely crystalline powder, odorless, with a somewhat sweetish taste. It is readily soluble in alcohol and in benzene, and crystallizes from the former in hexagonal tables with a melting point of 91.5° C. (196.7° F.). According to Guttman and to Kollmann (*Internat. Klin. Rundsch.*, Sept. 1890; also *M. M. W.*, Nov. 1890), it is an active antipyretic and antirheumatic, which rarely produces toxic symptoms, although an eruption resembling that caused by antipyrine has been noted; the color of the urine is not affected, but tests show the presence of salicylates. Kollmann states that it sometimes causes vomiting, and the daily dose should not exceed forty-five grains (3.0 Gm.), and always be less than this in the beginning, as some individuals are intolerant of it. Salipyrin has been used to a considerable extent in all forms of *rheumatic diseases*, in *influenza*, in various *fevers*, in *migraine*, and in the whole class of diseases in which its component constituents have been found to be useful; also locally in *coryza*. Salipyrin has been very highly praised by Beutner as a sedative antihemorrhagic remedy, in all forms of *metrorrhagia* not dependent upon severe organic disease, in threatened *abortion*, and in *dysmenorrhœa*. The usual dose is from seven to fifteen grains (0.45–1.0 Gm.), in capsule or tablet, repeated every three or four hours, but some clinicians prefer a single large dose of forty-five grains (3.0 Gm.).

Salitannol. $C_{14}H_{10}O_7$.—A condensation product of salicylic and gallic acids; it is a colorless powder, insoluble in water, ether, chloroform, and benzene, slightly soluble in alcohol, soluble in solutions of caustic alkalis. It is used as a surgical antiseptic.

Salithymol. *Thymol Ester of Salicylic Acid*. $C_6H_3(CH_3)(C_6H_7)O.COC_6H_4(OH)$.—This salt is prepared by acting on molecular quantities of sodium salicylate and thymol sodium with phos-

phorus trichloride. It is a colorless crystalline powder, of sweet taste, insoluble in water, very soluble in alcohol. It is used as an antiseptic. Dose, from fifteen to thirty grains (1-2 Gm.).

Salix. U. S. 1880.—Most of the species of the large genus *Salix* are possessed of similar medicinal properties. (For elaborate study of various willow barks see *Wellcome Chemical Research Laboratory Report*, No. 39.) *S. fragilis*, L. (*S. russelliana*, Sm.), which has been introduced into this country from Europe, is said by Sir James Smith to be the most valuable species. *S. purpurea*, L., a European species, is stated by Lindley to be the most bitter, and *S. pentandra*, L., is preferred by Nees von Esenbeck. Many native species are in all probability equally active with the foreign.

Salix alba, L., the species formerly recognized by the U. S. Pharmacopœia, the common European or white willow, is twenty-five or thirty feet in height, with numerous round spreading branches. The exstipulate leaves are alternate, upon short petioles, lanceolate, pointed, acutely serrate with the lower serratures glandular, pubescent on both sides, and silky beneath. The aments are terminal, cylindrical, and elongated, with elliptical-lanceolate, brown, pubescent scales. The stamens are two in number, yellow, and somewhat longer than the scales; the style is short; the stigmas two-parted and thick. The capsule is nearly sessile, ovate, and smooth. The white willow is now very common in this country. It flowers in April and May, and the bark is easily separable throughout the summer. That obtained from the branches rolls up when dried into the form of a quill, from one-twenty-fifth to one-twelfth of an inch in diameter, has a brown, more or less finely warty epidermis, is flexible, fibrous, and of difficult pulverization. The inner surface is brownish white, and smooth, the liber separating in thin layers. Willow bark has a feebly aromatic odor and a peculiar bitter astringent taste. It yields its active properties to water, with which it forms a reddish-brown decoction. Pelletier and Caventou found, among its ingredients, tannin, resin, a bitter yellow coloring matter, a green fatty matter, gum, wax, lignin, and an organic acid combined with magnesia. The proportion of tannin is so considerable that the bark has been used for tanning leather. The characteristic constituent of all species of willow, however, is *salicin*. (See *Salicinum*, p. 1078.) Robert W. Beck (*A. J. P.*, 1891, 581) has determined the relative percentages of salicin and tannin as follows:

	Salicin.	Tannin.
Leaves of <i>S. lucida</i> , Muhl.	0.30 per cent.	6.48 per cent.
Bark of <i>S. lucida</i> , Muhl.	1.09 " "	3.58 " "
Bark of <i>S. alba</i> , L.	0.56 " "	4.26 " "
Bark of <i>S. nigra</i> , Marsh.	0.73 " "	3.29 " "

Jowett and Potter made an examination of thirty-three samples of willow and poplar, and found in but one (*Salix discolor*, Muhl.) the related glucoside *salinigrin*, which Jowett had previously discovered in an unknown sample of willow bark. This compound has the formula $C_{13}H_{16}O_7$, and on hydrolysis yields glucose and meta-hydroxybenzaldehyde (*Wellcome Chem. Research Laboratory Report*, No. 28). The bark of the willow is feebly tonic, but it is at present never employed in regular medicine.

Salix nigra, Marsh. **Black Willow.** **Pussy Willow.**—The younger Michaux states that this is a strong bitter, and according to various ec-

lectic practitioners, its green aments or floral buds are a very active sexual depressant, useful in *spermatorrhœa*, in all forms of *sexual excitement*, and in the nervous disturbances of the menstrual period. From twenty to thirty minims (1.3-1.8 Cc.) of the fluidextract are to be given four times a day.

Salocreol is a preparation containing an ester of the various phenols of beechwood tar. It occurs as a fluid of neutral reaction, oily consistence, brownish color, and is almost completely odorless. It is almost insoluble in water, easily soluble in the various alcohols, ether, or chloroform. It is saponified by the alkalies and alcohols, and on prolonged exposure also by glycerin. In saponified solutions the addition of a trace of ferric chloride produces the violet colors characteristic of phenol and salicylic acid in neutral solutions. It is affirmed that it is readily absorbed by the skin and does not irritate it or stain it permanently. Salocreol has been used with success in the treatment of *rheumatism*, *gout*, *erysipelas*, and various inflammatory conditions of the lymph glands. (*Deutsche Aerzte Ztg.*, 1903, No. 4.)

Salol-Camphor.—When three hundred parts of salol are rubbed with two hundred parts of camphor, and then gently warmed, a liquid is obtained insoluble in water, but miscible with fixed and volatile oils, ether, and alcohol, to which Désesquelle has given the name of *salol-camphor*, and which he recommends as a local anæsthetic.

Salophen.—*Acetylparamidophenol Salicylate*, $C_6H_4 \begin{cases} OH \\ COOC_6H_4.NH(C_2H_5O) \end{cases}$, is formed by the combination of salicylic acid with acetylparamidophenol, and contains 51 per cent. of salicylic acid. It forms small white crystalline scales melting at 187° C. (368.6° F.), and is almost insoluble in cold water; moderately soluble only in alcohol and ether. In warm alkaline solution it undergoes decomposition into salicylic acid and acetylparamidophenol. According to Siebel (*Th. M.*, Jan. 1892) this reaction takes place in the intestines. The same authority also states that acetylparamidophenol is scarcely toxic, 8 Gm. per kilo being necessary to kill a rabbit. It has been used by various clinicians in all forms of *rheumatic diseases* and is undoubtedly effective, though less certain in its action than are the simple salicylates. It is also used to some extent as an analgesic in the pains of nervous diseases, in *pruritus*, and also as an intestinal antiseptic.

Dose, ten to fifteen grains (0.65-1.0 Gm.); not more than seventy-five grains should be given daily.

Saloquinine. *Salochinin.* $C_6H_4.OH.CO.O.$ $C_{20}H_{23}N_2O_5$.—*Quinine ester of salicylic acid* occurs in colorless crystals, insoluble in water, freely soluble in alcohol and ether, fusing at 130° C. (266° F.). It is tasteless and is said not to disturb the digestion or to cause tinnitus aurium, although it is very slowly absorbed. It is said to contain 70 per cent. of quinine, and has been used successfully as an antiperiodic, but is reputed to be of special value in the treatment of malarial and other *neuralgias*, also in fulgurant pains, and has also been highly commended in *typhoid* and other *fevers* as an antipyretic. If in a fever it be administered directly after the cold bath, it begins to powerfully impress the system about the time the effect of the immersion is going off. It may be given in the single dose of from fifteen to thirty grains (1-2 Gm.), repeated within twenty-four hours in bad cases of *rheumatic affections*.

Salubrol. *Tetra-bromo-methylene-di-antipyrine*. An inodorous powder, made by the action of bromine on methyl-antipyrine. It is non-poisonous, and is used as a local hæmostatic and antiseptic and as a substitute for iodoform.

Salumin. *Aluminum Salicylate*. $(C_6H_4(OH)COO)_3Al_2 + 3H_2O$.—This salt, which is insoluble in water, is made by the interaction of solutions of sodium salicylate and a salt of aluminum; it is a reddish-white powder used in catarrhal affections of the nose and pharynx. A soluble salumin is made by combining ammonia with the insoluble salumin, to form *ammoniated aluminum salicylate*, the formula of which is $(C_6H_4 \begin{Bmatrix} ONH_4 \\ COO \end{Bmatrix})_3Al_2 + 2H_2O$. It is used for preparing astringent and antiseptic washes.

Salvia.—Of this labiate genus one species, *S. officinalis*, is recognized by the U. S. P. 8th Rev., the article will be found on p. 1080. Many of the species share the feeble medicinal properties of the official drug. *S. pratensis*, *S. Æthiopis*, *S. glutinosa*, and *S. Sclarea*, or *clarry*, have been officially recognized in Europe, but are less agreeable than is *S. officinalis* and are not much used; the leaves of *S. Sclarea* are said to be introduced into wine in order to impart to it a muscadell taste. The infusion of the *Rocky Mountain sage*, probably *S. lanceolata*, W., is affirmed by A. Comstock (*T. G.*, 1887, 660) to be valuable as a diaphoretic in malarial and rheumatic fevers, taken in the form of hot infusion, and when cold to be distinctly tonic and astringent. The dose of fluidextract is half a fluidrachm (1.8 Cc.).

The seeds of various sages contain enough farinaceous and mucilaginous material to make them useful as food. In the Western United States the ordinary sages of the plains are highly esteemed for fattening cattle, which eat their ripened tops freely (these sages must be distinguished from the so-called "sage brushes" of the West, which belong to the genus *Artemisia*). *Chia* is the seeds of one or more species of *salvia* largely used in Mexico and Southern Arizona by the natives as food. It is affirmed that the variety known as *Chia pinoli* is yielded by *S. columbaria* (see Report U. S. Geogr. Surveys, 100th Merid., vol. vi. 48). *S. Chia* was described in the *Farmacopœa Mexicana* as a new species, yielding chia, but Mariano Báscena affirms (*La Naturaleza*, 1881) that the common chia-yielding sage of Mexico is *S. polystachya*, while *Chia azul* is yielded by *S. patens*. Guibourt is probably in error in ascribing chia to *S. hispanica*. The chia seeds are used not only when crushed as food and for the making of mucilaginous poultices, but also for the preparation of a mucilaginous drink, prepared by adding a teaspoonful of the seed to a tumblerful of cold water, allowing it to stand for half an hour, sweetening and flavoring to taste. They are described as follows: "The seed is a small one, about 1-16th inch in length, and 1-24th inch in width; oblong-ovate, somewhat flattish, nearly cylindrical, both ends rounded and slightly tapering; the thinner end has a small, dark line, forming a slight projection, which is the eye of the seed, and this, when exposed to moisture, opens in a star-shaped or scalloped manner, emitting the growing embryo. Below this eye are oil cells. The seed is smooth and glossy, and is surrounded by a transparent epithelium, swelling very largely when in water. The testa is darkish-gray, striated with dark brown lines, running diagonally, and dotted, forming a very beautiful variegated surface; when

pressed or crushed under a spatula it bursts at the hilum, exposing the cotyledons and the oil cells, leaving an oily stain upon paper. Internally the testa is dark, grayish-brown, perfectly smooth, glossy, and devoid of the external variegations or striae. It contains the embryo, with the radical pointing towards the hilum, and a white, mucilaginous substance much resembling unrendered fat." (*A. J. P.*, May, 1882, 227-229.) The European species, *Salvia verticillata*, Willd., *S. Verbenaca*, L., *S. horminum*, L., and *S. viridis*, L., all indigenous to Central or Southern Europe, are also noted for the mucilaginous character of their seeds, and have on this account been employed to remove foreign substances from the eye.

Samadera Bark.—This is the inner bark of a tree belonging to the family of Simarubaceæ, growing in Ceylon. It is intensely bitter, and probably contains quassin. For further particulars, see *P. J.*, 1872, 541.

Sandarach. *Sandaraca*. *Gum Juniper*. *Sandarake*, Fr. *Sandarak*, G.—A resinous substance obtained from the *Callitris quadrivalvis*, Vent. (*Thuja articulata*, Vahl.), an evergreen tree (Fam. Pinacææ) growing in Northern Africa. It is in small, irregular, roundish oblong grains or tears, of a pale yellow color, sometimes inclining to brown, more or less transparent, dry and brittle, breaking into powder under the teeth, of a faint, agreeable odor increased by warmth, and of a resinous, slightly acrid taste. It melts with heat, diffusing a strong balsamic odor, and easily inflames. It is almost entirely soluble in ordinary alcohol, and entirely so in that liquid when anhydrous, and in ether. Heated oil of turpentine also dissolves the greater part of it, but very slowly. According to Unverdorben, it consists of three resins, varying in their relations to alcohol, ether, and oil of turpentine. The *sandaracin* of Geise, which remains after sandarach has been exposed to the action of ordinary alcohol, is a mixture of two of these resins. Tschirch (*Harze und Harzbehälter*, p. 276) has isolated and described an acid, *sandaracolic acid*, $C_{44}H_{84}O_4(OH)COOH$, making up 85 per cent. of the natural resin and *callitric acid*, $C_{64}H_{82}O_5(OH)COOH$, of which 10 per cent. is present. In Australia and Tasmania *Callitris* trees grow in vast numbers, and produce a sandarach which is almost colorless, having highly refractive power, and a pleasant aromatic odor, becoming dark by age, and sometimes assuming a superficial mealiness. This Australian sandarach softens easily, but does not melt in boiling water, is gritty to the touch, and can scarcely be distinguished from the African drug. (*P. J.*, Jan. 1890.) For an elaborate description of Australian sandarach, see also *A. J. P.*, 1890, 215. Sandarach was formerly given internally, and entered into the composition of various ointments and plasters. At present it is used chiefly as a varnish and as incense; its powder, termed *pounce*, is rubbed upon paper to prevent ink from spreading after letters have been scratched out. A false sandarach has been described by R. Haneke. It resembled the real article, being lemon-yellow in color, transparent, and the tears elongated and rounded at the tips. When chewed it broke into fine powder and stuck to the teeth, while it softened on the water bath and flowed together into a resinous mass. Examination showed it to consist largely of colophony. (*O. Z.*, liv.)

Sanicula. *Sanicula marylandica*, L. *Sanicle*. *Saniole*, Fr. *Sanikel*, G.—The root of this in-

digenous umbellifer is popularly known in some parts of the country by the name of *black snake-root*. It is fibrous and of an aromatic taste, and, according to C. I. Houck (*A. J. P.*, vol. xiv. 463), contains a volatile oil and a resin. It has been used in *intermittent fever*, and also in *chorea* by Zabriskie; dose of powder to children eight years old half a drachm (2.0 Gm.) three times a day. (*Am. J. M. S.*, N. S., xii. 374.)

Sanoform. Di-iodo-methyl Salicylate.

$\text{C}_6\text{H}_2\text{COOCH}_3$
 $\text{C}_6\text{H}_2\text{OH}$
 I_2 . This substance is obtained by

the action of iodine on methyl salicylate (oil of wintergreen). It is a crystalline, colorless, odorless, and tasteless powder, permanent in the light and air, and melting at 110° C. (230° F.), but may be heated up to 200° C. (392° F.) without decomposing. It is soluble in 200 parts of cold or 10 parts of hot alcohol, and readily in ether, chloroform, benzene, and carbon disulphide, but almost insoluble in water or glycerin. It contains 62.7 per cent. of iodine. It forms with caustic alkalies, salts which are sparingly soluble in water.

Sanoform, first introduced as a substitute for iodoform by A. Arnheim, would appear to afford an efficient antiseptic dressing for wounds. As it remains unchanged at high temperatures, it is readily sterilized, while its odorlessness gives it a great advantage over iodoform. Its absorption is extremely slow, as it does not appear in the urine after having been administered hypodermically until twenty-four hours have elapsed, and does not entirely disappear until after fourteen days. It is seemingly, therefore, less poisonous than iodoform. It may be used as a dusting powder or in the manufacture of a 10 per cent. gauze which can be sterilized by heating; or a 1 per cent. solution in collodion, or a 10 per cent. ointment may be employed. It has been employed with satisfaction in ophthalmic surgery by Radziejewski and by Jacobsohn.

Santolina.—A composite plant, *Santolina Chamæcyparissus*, L., is stated to have long been used popularly against the round worm in Scotland. It has been analyzed by T. Maben (*P. J.*, xvi. 301), who finds in it a volatile oil and a considerable percentage of resin, with a bitter principle, which he believes to be an alkaloid and the active principle of the drug. The decoction of the plant may be made by boiling half an ounce in a pint of water for half an hour, straining and making up to a pint. It is given in doses of five fluidounces (150 Cc.) to adults and half that quantity to children, repeated for four mornings, and then followed by a brisk cathartic.

Santoninnoxime. $\text{C}_{15}\text{H}_{13}\text{O}_2\text{N}\cdot\text{OH}$.—This substance was first prepared in 1889 by P. Guici (*Gazz. Chim.*, xix. 367) by digesting at nearly 80° C. (176° F.) for three days five parts of santonin, four parts of hydroxylamine hydrochloride, fifty parts of strong alcohol, and four parts of precipitated calcium carbonate. It crystallizes in white silky needles, melts at about 217° C. (422.6° F.), is very slightly soluble in hot water, and turns the plane of polarized light to the left. Coppola states that this substance is a safe and reliable substitute for santonin, to be given in doses about three times as large.

Sapindus.—Various tropical plants belonging to this genus of the Sapindaceæ contain saponin, and are largely used for cleaning purposes. Thus, in India are employed the pulp of the fruit of *Sapindus Mukorossi*, Gaertn. (*S. detergens*, Roxb.),

the capsules of *S. trifolius*, L. (*S. emarginatus*, Vahl., *S. laurifolius*, Vahl.), and in South America the oil and seed vessels of *S. Saponaria*, L. (*P. J.*, 1871, 585.) For the properties of saponin, see *Saponaria officinalis*, below.

Sapium. *Sapium sebiferum* (L.), Roxb. (*Croton sebiferus*, L., *Stillingia sebifera*, Michx.) *Tallow Tree*. *Tankawang Fat*.—This is a species of the family Euphorbiaceæ, cultivated in the Chinese provinces of Kiangse, Kiang-sou, and Chih-kiang for the sake of the fatty matters extracted from the nuts by methods detailed in *A. J. P.*, 1872, 264. (See *P. J.*, June, 1872.) The "tallow" occurs in hard, brittle, opaque, white, tasteless, and odorless masses of about eighty pounds' weight. It is said to be nearly pure stearin. The oil is largely used for lighting purposes. The remnants of the nut are employed as fuel and as manure. (See also *P. J.*, 1883, 401, and *Ibid.*, 1887, 901.)

Sapolan.—This is a brownish-black ointment, consisting of two and one-half parts of naphtha, one and one-half parts lanolin, and 3 to 4 per cent. anhydrous soap; used as a stimulant ointment in various skin diseases.

Saponaria. *Saponaria officinalis*, L. *Soapwort*. *Saponaire*, *Savonnaire*, Fr. *Seifenwurz*, G. (Fam. Caryophyllaceæ).—A perennial herbaceous plant, growing wild in this country in the vicinity of cultivation, but introduced from Europe. It is commonly known by the vulgar name of *bouncing bet*. It is one or two feet high, with smooth, lanceolate leaves, and clusters of conspicuous whitish or slightly purplish flowers, which appear in July and August. The root and leaves are employed. They are inodorous, and of a taste at first bitterish and slightly sweetish, afterwards somewhat pungent, continuing long, and leaving a slight sense of numbness on the tongue. They impart to water the property of forming a lather when agitated, like a solution of soap, whence the name of the plant was derived. This property, as well as the medicinal virtues of the plant, resides in *saponin*, $\text{C}_{32}\text{H}_{54}\text{O}_{18}$. This principle constitutes, according to Bucholz, its discoverer, 34 per cent. of the dried root, which contains also a considerable quantity of gum and a little bassorin, resin, and altered extractive, besides lignin and water. Saponin is obtained, though not absolutely pure, by treating the aqueous extract with alcohol and evaporating. When thoroughly purified (see *A. J. P.*, 1884, 274), it is a very white, amorphous, inodorous powder, which excites sneezing when inhaled by the nostrils, has a pungent, disagreeable taste, and is poisonous. It is soluble in water and official alcohol, but is insoluble in anhydrous alcohol, ether, and the volatile oils. Although a glucoside, according to Lautenbach (*Journ. Nerv. and Ment. Dis.*, 1879, 433), it unites with sulphuric acid to form long acicular crystals. Its aqueous solution froths when agitated. It is decomposed by dilute acids, though with some difficulty, into *sapogenin*, $\text{C}_{14}\text{H}_{22}\text{O}_8$, and sugar, or, according to Schiaparelli (*A. J. P.*, 1884, 275), into *saponetin*, $\text{C}_{40}\text{H}_{66}\text{O}_{15}$, and sugar, according to the reaction:

$2\text{C}_{32}\text{H}_{54}\text{O}_{18} + 3\text{H}_2\text{O} = \text{C}_{40}\text{H}_{66}\text{O}_{15} + 4\text{C}_6\text{H}_{12}\text{O}_6$
 Stiltz (*Ann. Ch. Ph.*, 218, 250) studied the saponin from *Quillaia Saponaria*, Mol., and, after purifying his preparation and making a series of acetyl derivatives therefrom, was led to give the formula $\text{C}_{16}\text{H}_{30}\text{O}_{10}$ to saponin. It has been found in many other plants, among them some species of *Silene*, *Dianthus*,

and *Lychnis*, in *Vaccaria vulgaris*, Host., and in *Agrostemma Githago*, L., all these belonging to the fam. Caryophyllaceæ. (*J. P. C.*, 3e sér., x. 339; also *P. J.*, 1871, 585; *Australian Journ. Pharm.*, 1887.) Serious poisonings by the mixture of the seeds of *Agrostemma Githago* with wheat have been reported. (*D. M. W.*, 1903.) According to Augustine Henry, there are at least eleven species of trees whose products are used in China for washing purposes and probably contain saponin, which is also found to the extent of 10 per cent. in the seeds of the Chinese tea oil tree, and is left in such large proportion in the refuse after the extraction of the oil that the "tea seed cake" is used as a fish poison. (*Am. Drug.*, 1896.) In California the *Indian Soap Root*, *Chlorogallum pomeridianum* (Ker.), Kunth., is much used for washing clothes; it probably contains saponin. The fruits of various species of *Sapindus* are also rich in saponin and are used as detergents accordingly. In diluted form saponin is irritant to all tissues, and when concentrated it kills by its local action both muscular and nervous tissue. As was first discovered by H. Köhler, when injected into the leg of the frog in minute quantity it produces not only motor weakness but a rapid loss of sensibility, so that reflex movements can no longer be caused by irritating the foot. The paralysis seems to affect especially the peripheral nerve endings, since irritation of the nerve trunk, although incapable of causing contraction of the muscles supplied by it, elicits pain cries and other evidences of sensibility. Muscles with which saponin comes in contact become unexcitable and pass into a condition resembling post mortem rigidity. According to Köhler, this occurs without change in the microscopic structure, but Przybyszewski found that in the neighborhood of the injection where the saponin was abundant the muscles underwent structural changes similar to those of myositis. In the frog saponin produces not only local symptoms, but after a time wide-spread paralysis, with final arrest of the cardiac movements. Given internally to mammals it causes violent gastro-intestinal irritation, progressive loss of power, disturbance of respiration and circulation, and usually clonic and tonic convulsions, which are probably secondary to the perturbations of the cardiac and respiratory functions. Lohmann (*P. J.*, 73, 477) affirms that chemically pure saponin is not injurious when taken by the stomach. Injected into the circulation in rabbits and dogs, according to the researches of Przybyszewski, it causes fall of the arterial pressure, with great disturbance of the respiration and finally cardiac arrest. According to Köhler, the action of the drug upon the heart is antagonistic to that of digitalin, so that the application of sufficient quantities of saponin to the frog's heart which has been arrested by the local application of digitalin will bring about a return of pulsations, while, on the other hand, digitalin is capable of putting aside cardiac arrest from saponin. As has been shown by Ransom (*D. M. W.*, xxvii.), saponin has a powerfully destructive action upon the red blood corpuscles, due to an extraordinary tendency which it has to unite with their cholesterol. The action of saponin upon the respiratory centres is very great, the injection of large doses being followed by immediate arrest of respiration, the heart continuing to beat for some time. As it exists in *agrostemma* seeds, saponin has several times caused death in the human species. The symptoms have been headache, vertigo, vomiting,

hot skin, rapid feeble pulse, progressive muscular weakness, and finally coma. Following out the experiments of Kobert, Ulenburg and Keppler tried saponin as a local anæsthetic, but found that it was not practically convenient for use; nor were the essays of Kobert with the glucoside as an antipyretic more encouraging. Senega appears to depend upon saponin for whatever expectorant virtues it may possess, and the use of quillaia bark has been strongly urged by Kobert. (See *Quillaia*, p. 1035.) In Germany soap root has been used as a substitute for sarsaparilla in scrofulous, venereal, and cutaneous affections, and also by Andri in the form of inspissated juice, half an ounce a day, in *gonorrhœa*. The dose of the decoction is set down at two pints daily. For further information as to the physiological action of saponin, consult Husemann's *Pflanzenstoffe*, second edition, and *S. Jb.*, xxi. 3, 13.

According to Kobert (*Gaz. Méd. de Paris*, xiv. 2, 1883), saponin of commerce is composed chiefly of two substances, *quillaia acid* and *sapotowin*. For method of preparation, see *T. G.*, vol. ii. 540. The quillaia acid is said to be extraordinarily poisonous, three-one-thousandths of a grain for each pound of body weight injected into the veins of a cat being sufficient to cause death, although thirty grains administered by the mouth are safely borne.

Sappan.—The heart wood of *Cæsalpinia Sappan*, L. Under the name of *patang*, sappan wood is largely used as a dye in India, and has long been employed in the British India Medical Service as a substitute for logwood. It is officially characterized as occurring in hard, heavy sections of variable size, or in the form of chips, of a fine orange-red color. A transverse section exhibits well marked concentric rings, numerous narrow medullary rays, and large vessels which are readily seen with a lens. It is cut with difficulty transversely, but is easily split longitudinally, showing distinctly the grain due to the medullary rays. The wood has no odor, and only a slightly astringent taste. It communicates a red color to alcohol (90 per cent.) and to water; this color becomes a carmine red, and not purple, upon the addition of solution of potassium hydroxide (distinction from logwood). According to the investigations of Bolley, sappan wood contains *brasilin*, $C_{16}H_{14}O_5$, identical with that of Brazil wood. Internally it is used in India as an astringent in the treatment of *diarrhœa*. The Br. Add. recognizes a *decoction* (*Decoctum Sappan*, Br. Add.), one ounce with seventy grains (4.5 Gm.) of cinnamon bark to the pint; dose, from one-half to two fluidounces (15-60 Cc.).

Saprol. Disinfection Oil.—A mixture of crude cresols, containing pyridine bases and hydrocarbons, used for disinfecting purposes. As it is inflammable, care should be exercised in its use.

Sarcocolla. Sarcocolle, Fr. Fleischleimgummi, Fischleimgummi, G.—A peculiar vegetable product, exuding spontaneously from various species of the genus *Penæa* (Fam. *Penæaceæ*), small shrubs growing at the Cape of Good Hope, in Ethiopia, Arabia, etc. It is in the form of small, roundish, irregular grains, sometimes agglutinated in masses, friable, opaque or semi-transparent, of a yellowish or brownish-red color, inodorous unless heated, when they have an agreeable odor, and of a peculiar, bitter, sweetish, and acrid taste. *Sarcocolla*, according to Pelletier, consists of 65.3 per cent. of a peculiar substance, considered by Thomson as holding an intermediate place be-

tween gum and sugar, and called *sarcocollin*, $C_{18}H_{22}O_8$, 4.6 of gum, 3.3 of a gelatinous matter having some analogy with bassorin, and 26.8 of lignin, etc. It is said to be purgative, but at the same time to produce serious inconvenience by its acrid properties. The Arabian physicians used it internally, and by the ancients it was employed as an external application to wounds and ulcers, under the idea that it possessed the property of agglutinating the flesh, whence its name.

Sarracenia. *Side-saddle Plant. Fly Trap. Pitcher Plant. Huntsman's Cup. Water Cup.* *Sarracenia*, Fr., G.—According to E. P. Porcher, the roots of *Sarracenia flava*, L., and *S. variolaris*, Michx., have long been used in the Southern United States in *dyspepsia*, and are tonic, laxative, and diuretic. Sheppard found them to contain lignin, coloring matter, resin, an acid salt of lime, and probably an alkaloid. Stan. Martin asserts that he has found in the root,—1, an alkaloid which he proposes to name *sarraceniine*; 2, a resin; 3, a yellow coloring principle (probably identical with Schmidt's *sarracenic acid*); 4, extractive; 5, substances which constitute the framework of plants. *Sarraceniine* is white, soluble in alcohol and ether, combines with acids to form salts, and with sulphuric acid forms handsome needles, which are bitter, and communicate this taste to its menstrua. (*Ann. Thér.*, 1866, 73.) E. Schmidt, however, found no alkaloid, but discovered *sarracenic acid*. (*A. J. P.*, 1872, 213.) *Dose*, of tincture (two ounces in one pint), a fluidrachm (3.75 Cc.); of fluidextract, from ten to twenty minims (0.6–1.3 Cc.).

Sassy Bark. *Mancona Bark. Saucy Bark. Ecorce de Mançoine*, Fr. *Manconarine*, G.—This bark is interesting chiefly from its employment by the natives of Western Africa as an ordeal in their trials for witchcraft or sorcery. (For details, see *P. J.*, lxx. 2.) This bark was first studied by C. A. Santos (*A. J. P.*, 1849, xxi. 97), and subsequently by Procter (*Ibid.*, xxii. 301; xxiv. 195), who proposed the name of *Erythrophileum judiciale* for the tree yielding it. The tree had, however, been previously described under two specific names, having been noted in Hooker's *Niger Flora* (p. 329) as the *Erythrophileum guineense* of Don, and being also the *Fillæa suaveolens* of Guillemain and Perottet's *Flora of Senegal*. It is a large tree with spreading branches, doubly pinnated leaves, flowers in spike-like racemes, and leguminous fruit. The bark is in pieces more or less curved, with or without epidermis, in the former case somewhat fissured externally, of a dull red color diversified by whitish spots, brittle, presenting when cut transversely numerous fawn-colored spots surrounded by reddish-brown tissue, nearly inodorous, and of an astringent taste.¹ Gallois and Hardy obtained the poisonous principle *erythrophleine* by making an alcoholic extract of the bark, exhausting this with water, evaporating, rendering this extract alkaline with ammonia, and treating with acetic ether. The alkaloid is a colorless, crystalline solid, soluble in water, acetic ether, alcohol, and amyl alcohol, insoluble in chloroform, benzoin, and ether. In contact with sulphuric acid and black manganese oxide, a violet color (less intense than that pro-

duced with strychnine) is developed. Harnack and Zabrocki (*A. E. P. P.*, xv. 404) also prepared *erythrophleine*, and by the action of hydrochloric acid upon it obtained an acid they call *erythrophleic acid*, and a volatile alkaloid they call *mangonine*. The bark yields its virtues to water.

According to the observations of Savage, made in Africa (*Charleston Med. Journ.*, 1859), sassy bark produces in the natives a feeling of constriction in the fauces, attended by prickling, and followed by numbness, with, after a toxic dose, stricture across the brow, severe pain in the head, coma, and death. The physiological action of *erythrophleine* has been studied by various observers, especially by E. Harnack and R. D. Zabrocki, Gallois and Hardy, and Lauder Brunton, with results which are fairly concordant. It has a pronounced action upon the circulation, causing a slow strong pulse, with a rise in the arterial pressure; phenomena which are certainly in great part due to the direct action upon the ganglionic structure or muscular fibre of the heart itself, but which are also seemingly in part produced by a stimulating influence upon the muscle fibres or nerves in the walls of the arterioles. The action, therefore, of *erythrophleine* would seem to be very close to that of the digitalis principles. Purging was also noted as the result of an increased peristalsis, thought to be due to the local action of the poison. Vomiting is believed by Lauder Brunton to be the result of an influence upon the nerve centres, because it occurs when the alkaloid is given hypodermically. In fatal poisoning in the lower animals, convulsions are pronounced, and the respiration is also markedly affected. In 1888 L. Lewin asserted *erythrophleine* to be a powerful local anæsthetic, whose action is more pronounced than that of cocaine. His paper gave rise to an extraordinary controversy, the outcome of which appears to be that, although the alkaloid is possessed of not very active anæsthetic powers, it is for various reasons practically not useful. (See 17th edition, *U. S. D.*, p. 1739.) A solution of the strength of one-tenth of one per cent. is used as an application to the cornea.

Germain Sée asserts (*Méd. Mod.*, Dec. 1891) that, although sassy bark does not act well upon the heart, it gives great relief in *dyspnoea*, the number of respirations being lessened and the inspirations being extraordinarily increased in depth. He gave of the alkaloid from 1-40th to 1-30th of a grain (0.0016–0.002 Gm.); of the extract, from $\frac{1}{4}$ to $\frac{1}{2}$ of a grain (0.016–0.021 Gm.).

Satureia. *Satureia hortensis*, L. *Summer Savory. S. Montana*, L. *Winter Savory. Sarriette*, Fr. *Saturei, Bohnenkraut*, G.—Annual labiate plants resembling thyme in odor and flavor, growing spontaneously in the south of Europe, and cultivated in our gardens as culinary herbs.

Saururus. *Saururus cernuus*, L. *Lizard's Tail*. (Fam. Saururaceæ.)—D. L. Phares of Newtonia, Miss., considers this indigenous swamp plant "laxative, antispasmodic, sedative, and slightly astringent;" useful in irritation of the kidneys, bladder, prostate, and urinary passages generally. The *dose* of the strong infusion was, with the plant either fresh or dried, from one to four fluidounces (30–120 Cc.) every fifteen or thirty minutes, or three or four times a day. (*A. J. P.*, 1867, 468.)

Saxifraga.—Garreau and Machelast have isolated from *S. crassifolia*, L. and other species of

¹ A comprehensive description of sassy bark is given in the *Commentar zur oesterreichischen Pharmacopœia*, 1880, by Vogel; while in the *Résumé de la Matière Médicale et Toxicologique Coloniale*, by Corre and Lejanne, the plant, fruit, seeds, etc., are carefully illustrated.

this genus a crystallizable bitter substance, *bergenin*. It is obtained by boiling the stems of the plants with absolute alcohol, after the tannin has been removed by ether. It crystallizes in alcohol, has a bitter taste, melts at 140° C. (284° F.), and burns up completely at 300° C. (572° F.). It is soluble in 167 parts of 90 per cent. alcohol and in 830 parts of water, but is more soluble in these liquids at a boiling temperature; it is faintly acid to litmus, and is not changed by treatment with dilute sulphuric or hydrochloric acid, but by diluted nitric acid is converted into oxalic acid. Concentrated sulphuric acid decomposes it. Its formula is given as $C_6H_3O_3.H_2O$. *Bergenin* is asserted to be intermediate in its action between salicylic acid and quinine. (*A. Pharm.*, 1881, 293.) The rhizome of *Sacifraga ligulata*, Wall., which is used in India in *dysentery*, has been found by David Hooper to contain about 16 per cent. of gallic and tannic acids, but no other active principles. (*P. J.*, Aug. 1888.)

Schinus. *Schinus molle*, L. (Fam. Anacardiaceæ.)—The *pepper tree* of South America yields a berry the size of a pea, having a flavor similar to a mixture of pepper and fennel. It has been introduced as a shade tree in Southern California. (*A. J. P.*, 1896, 215.) Schimmel & Co. examined the volatile oil distilled from the berries; it had the sp. gr. 0.850, the odor of phellandrene, and was soluble in alcohol. (*Ph. Rev.*, 1897, 114.) It has been used successfully in *gonorrhœa* as a substitute for cubeb. The leaves, bark, and gum resin have been employed medicinally. (See *A. J. P.*, 1866, 1885, 1890; also *P. J.*, 1887.)

Schleich's Anæsthetic Mixture.—In 1895 Schleich proposed the use of an anæsthetic mixture based upon the theory that the ideal anæsthetic should have a boiling point as near as possible to the temperature of the human body, so that elimination should take place from the lungs as rapidly as possible, with consequent immediate awakening from unconsciousness. Schleich's mixtures, three in number, are,—

Mixture No. 1.—Boiling point, 100.4° F. Chloroform, 45 Cc.; petroleum ether, 15 Cc.; ether, 180 Cc.

Mixture No. 2.—Boiling point, 104° F. Chloroform, 45 Cc.; petroleum ether, 15 Cc.; ether, 150 Cc.

Mixture No. 3.—Boiling point, 107.6° F. Chloroform, 30 Cc.; petroleum ether, 15 Cc.; ether, 80 Cc.

Of these mixtures No. 1 is the most evanescent and produces the briefest anæsthesia, while No. 3 is the most permanent in its action.

The incorrectness of the assertion of Schleich, that *petroleum benzin* is a neutral diluent, has been demonstrated by H. C. Wood, Jr., in a series of experiments (*P. M. J.*, April, 1899), in which he proved that petroleum benzin acts both upon the heart and the vasomotor system as a paralyzant, and that its effect upon the respiratory centre is even more powerful, while its anæsthetic influence is exceedingly feeble. It would appear, therefore, that the use of Schleich's mixture is attended by more danger than is that of either chloroform or ether, a conclusion which seems to be borne out by the analysis of about one thousand reported cases made by him.

Scolopendrium. *Scolopendrium Scolopendrium* (L.), Karst. *Asplenium Scolopendrium*, L. *Phyllitis Scolopendrium* (L.), Newman. *Hart's Tongue.*—The fronds of this fern, which

is indigenous both in Europe and America, have a sweetish, mucilaginous, and slightly astringent taste, and, when rubbed, a disagreeable oily odor. They were used as a deobstruent in visceral affections, as an astringent in *hemorrhages* and *fluxes*, and as a demulcent in pectoral complaints.

Scrophularia. *Scrophularia nodosa*, L. *Figwort.* *Scrofula* Plant. *Scrofulaire*, Fr. *Kropfwurz*, *Knotenwurz*, G. (Fam. Scrophulariaceæ.) Its leaves have when fresh a rank fetid odor, and a bitter, somewhat acrid taste; but these properties are diminished by drying. Water extracts their virtues, forming a reddish infusion, which is blackened by ferric sulphate. For histological study of root, see *P. J.*, 1896. Walz has obtained from it two proximate principles, which he names respectively *scrophularin* and *scrophularosmin*. (Mayer, *A. J. P.*, 1863, 295.) Figwort leaves were formerly considered tonic, diuretic, diaphoretic, discutient, antihelmintic, etc.; useful in *scrofula* and as a local application in *hemorrhoids*. Van de Moer (*P. J.*, 1896) affirms that the seeds are toxic, belonging to the digitalis group.

Sedatin. *Para-valerylphenetidin*, is made by the action of phenetidin hydrochloride upon sodium valerate; it occurs in fine crystals. It is soluble in hot alcohol, sparingly soluble in ether, chloroform, and petroleum benzin. It is said to act like antipyrine.

Sedum. *Sedum acre*, L. *Biting Stonecrop.* *Wall Pepper.* *Small Houseleek.* *Mossy Stonecrop.* *Joubarbe acre*, *Povvre des Murailles*, Fr. *Mauerpfeffer*, *Steinkraut*, G. (Fam. Crassulaceæ.) This European plant has escaped to some extent from the gardens and grows wild in New England. It causes vomiting and purging, and applied to the skin produces inflammation and vesication. The fresh herb and the expressed juice have been used as an antiscorbutic, emetic, cathartic, and diuretic, and have been applied locally to old *ulcers*, *warts*, and other excrescences. Other species are less acrid, and are even eaten as salad in some parts of Europe. Such are *Sedum rupestre*, L., and *S. album*, L. *S. Telephium*, L., was formerly employed externally to cicatrize wounds, and internally as an astringent in *dysentery* and *hæmoptysis*, and is still esteemed by the common people in France as a vulnerary. Ernst Mylius found in 100 parts of *Sedum acre* 2.2 parts of a soft, not acid resin, 12.80 parts of uncrystallizable sugar, and 12.40 parts of a soft acid resin, besides an alkaloid and inert substance. (*J. P. C.*, 4e sér., xvii. 81.)

Selenium. Se = 78.6.—This widely distributed element, discovered by Berzelius in 1817, belongs to the sulphur group, and its compounds occur in nature associated with sulphur compounds. It is most conveniently extracted from the lead chamber deposits of the sulphuric acid works. The physiological actions of the compounds of this metal have not been widely studied, but Chabré and Sépique (*C. R. A. S.*, ex.) have shown that *selenous acid* is an irritant poison. According to Merck, a solution of selenous acid (0.5 per 100) is a valuable reagent for detecting alkaloids (*M. R.*, 1900).

Semecarpus. *Semecarpus venenosa*, the *Tschongott Tree.*—The highly poisonous bark of this tree, which is a native of the Caroline Islands, is, according to Thoms and Mannich (*Ph. Ztg.*, 1902), due to the presence of *cardol* (anacardic acid).

Sempervivum. *Sempervivum tectorum*, L. *Common Houseleek.* *Grande Joubarbe*, Fr. *Haus-*

wurz, Hauslauch, Dachwurz, G. (Fam. Crasulaceæ).—In Europe the bruised recent leaves of this plant are employed as a cooling application to burns and other external inflammations. The juice is said to cure warts.

Senecio.—Various species of this composite genus have been domestically used in the treatment of *amenorrhœa* both in Europe and America, and their value has been confirmed by various practitioners. (See *P. J.*, Dec. 1897.) The species specially used have been *Senecio vulgaris*, L., *Common Groundsel*, *Senegon*, Fr., *Kreutzkraut*, *Jacobskraut*, G.; an annual European plant introduced into this country and growing in cultivated grounds, and the North American species, *S. aureus*, L., or *ragwort*. The fluidextract is especially used in the dose of one fluidrachm (3.75 Cc.) three to six times a day.

In *S. vulgaris*, and in lesser amount also in *S. jacobæa*, A. Grandval and H. Lajoux (*Union Médicale du Nord-est*, xix. 1895) have found two alkaloids, *senecionine*, $C_{18}H_{26}NO_6$, which is slightly, and *senecine*, which is readily soluble in ether. According to Wiet, *senecionine* is a paralyzant of the peripheral motor and sensory nerves, while Bunch has found that the alcoholic extract of *Senecio jacobæa* is capable of producing a rise of the arterial pressure due to contraction of the arterioles, followed, if the dose has been large enough, by arterial dilatation with fall of pressure (*B. M. J.*, 2, 1900, 212). *Senecine* of the eclectic practitioners is made by precipitating the tincture with water and is not therefore a pure active principle.

The rhizomes of the Mexican species, *Senecio grayanus*, Hemsl., and *S. cervicariæfolius*, Hemsl., constitute *maturin*, the plants being known as *matarique*, *maturin*, or *guereña*. They produce rise of temperature, dilatation of the pupil, and violent tetanic spasms. Henckel states that they contain a glucoside resembling digitalin. (*A. J. P.*, Jan. 1891; also *Nouv. Rem.*, 1888, and *P. J.*, March, 1889.)

Septoform is a condensation product of formaldehyde with members of the terpene, naphthalene, and phenol groups, prominent among which is *diöxynaphthylmethane* ($C_{20}H_{20}O$)₂.CH₂. This preparation is offered in the form of a soap and also of an aqueous solution. It is said to be free from irritant properties and to be so strongly germicidal that a 1 per cent. solution will kill the cholera vibrio in five minutes, and the 3 per cent. solution the pus organism in three minutes. It has been chiefly used in veterinary practice, and for the disinfection of the hands (a 3 per cent. solution), or of instruments (5 to 10 per cent. solution). (*Th. M.*, xvi.)

Sesamum. *Sesamum indicum*, L. (Fam. Pedaliaceæ).—The benne plant of our Southern States is annual, with a branching stem four or five feet high, and bearing opposite, petiolate leaves, varying considerably in their shape. Those on the upper part of the plant are ovate-lanceolate, irregularly serrate, and pointed, those near the base three-lobed and sometimes ternate, and lobed leaves are not uncommon at all distances from the ground. The flowers are reddish-white, and stand solitarily upon short peduncles in the axils of the leaves. The fruit is an oblong capsule, with small, oval, yellowish seeds.

There are some ten or twelve species referred to the genus *Sesamum*, the majority of which are natives of Africa. In India one or two species occur wild, one of these, *Sesamum indicum*, L.

(*S. orientale*, L.), has been cultivated from time immemorial in various parts of Asia and Africa. From the latter continent it is supposed that seeds were brought by the negroes to the United States, where, as well as in the West Indies, it is now cultivated to a considerable extent. The plant above described will grow as far north as Philadelphia. The seeds are employed as food by the negroes, who parch them over the fire, boil them in broths, make them into puddings, and prepare them in various other modes. By expression they yield a fixed oil, which was introduced into the Pharmacopœia at the revision of 1880. Berjot obtained from the seeds 53 per cent. of oil by means of carbon disulphide.

Benne Leaves.—These abound in a gummy matter, which they readily impart to water, forming a rich, bland mucilage, much used in the Southern States as a drink in various complaints to which demulcents are applicable, as in *cholera infantum*, *diarrhœa*, *dysentery*, *catarrh*, *acute cystitis*, *strangury*, etc. The remedy has attracted attention also in the North, and has been employed with favorable results in Philadelphia. One or two fresh leaves of full size, stirred about in half a pint of cool water, will soon render it sufficiently viscid. With dried leaves hot water is used. The leaves also serve for the preparation of emollient cataplasms.

Sethia. *Sethia acuminata*, Arn.—The juice of this Ceylon plant or the powdered leaves—dose, fifteen grains (1.0 Gm.)—are affirmed to be an efficient vermifuge. (*P. J.*, April 7, 1883.)

Sida. *Sida rhombifolia*, L.—Queensland hemp (Fam. Malvaceæ), jelly leaf, is largely used in Australia as a demulcent. It contains a large quantity of mucilage. *Sida paniculata*, L. (*S. floribunda*, H. B. K.), of Peru, which also contains a large quantity of mucilage, is said by Martinet to be a very active vermifuge, owing its powers, probably, to the extremely minute but very resisting spines which cover its leaves, the part used.

Siegesbeckia. *Siegesbeckia orientalis*, L. (Fam. Compositæ).—This plant is used in the Mauritius Islands in *syphilis*, *leprosy*, and various skin diseases. A white, crystalline principle, *darutynine*, has been discovered in it by M. L. Auffray. (*P. J.*, vol. xvi. 1047; also *B. M. J.*, June 25, 1887.)

Sienna. *Terra di Sienna*.—An argillaceous mineral, compact, of a fine texture, very light, smooth, and glossy, of a yellowish-brown or coffee color, leaving a dull orange trace when moistened and drawn over paper. By calcination it assumes a reddish-brown color, and is then called *burnt sienna*. In both the raw and burnt states it is used in painting. The best sienna is brought from Italy, but an inferior kind is found in England.

Silene. *Silene virginica*, L. (Fam. Caryophyllaceæ.) *Catchfly*. *Wild Pink*.—The wild pink of West Virginia and the Carolinas was considered by the Indians poisonous and by Barton an anthelmintic.

Silex, Pulverized. *Silex Contritus*, Lond. *Silicio Acid.*—For mechanical purposes, in the making of aromatic waters, etc., the London Pharmacopœia formerly recognized under the name of *Silex Contritus* powdered quartz; but at present powdered purified talc, paper pulp and magnesium carbonate are employed. For details, see 17th edition, *U. S. D.*, p. 1741.

Pulverized silex is a harsh, white, tasteless powder, insoluble in water and most other solvents.

Its sp. gr. is 2.66. In composition it is a *silicio oxide*, SiO_2 . *Silicon* is an electro-negative element, which has been obtained in two allotropic states, called amorphous and crystalline silicon; the first corresponding to amorphous carbon and the second to crystallized carbon or the diamond, except that it is steel-gray in color. The second variety is hard enough to scratch glass but not topaz and has the sp. gr. 2.49. It is now made on a large scale as a product of the electric furnace, being used as a deoxidizing agent in the casting of some metals. Pure *silica* is easily prepared by acidulating commercial solution of sodium silicate with hydrochloric acid, heating and evaporating, and washing the precipitated silica.

Silphium. *Silphium laciniatum*, L. *Polar Plant*. (Fam. Compositæ.)—The *rosi weed*, or *compass plant*, of Ohio, yields an oleoresin, which is said to be used in making chewing gum. (A. J. P., 1881, 487.)

Silver Acetate. *Argenti Acetas*, $\text{AgC}_2\text{H}_3\text{O}_2$. This salt occurs in white crystals freely soluble in hot water. It has been introduced by Zweifel (*Centralbl. f. Gynäkologie*, 1900, No. 51) as a substitute for silver nitrate in the treatment of *ophthalmia* of new-born infants. He asserts that the one per cent. solution is in these cases much more effective than the older salt.

Silver Ammonio-chloride. *Argenti Ammonio-chloridum*. *Argentum Chlorato-ammoniatum*.—This substance is formed by saturating solution of ammonia, by the aid of heat, with silver chloride and allowing the liquid to cool in a stoppered bottle. It crystallizes in cubes. Silver ammonio-chloride has been used in the treatment of *chorea*, *epilepsy*, and *syphilis*, and as an anthelmintic, in doses of from one-twelfth to one and a half grains (0.005–0.1 Gm.). It is probably of little value.

Silver Chloride. *Argenti Chloridum*. AgCl . This is readily prepared by adding a solution of sodium chloride to one of silver nitrate, as long as it produces a precipitate. As first thrown down, it is a white, curdy substance, but it soon becomes discolored when exposed to the light. It is decomposed by solutions of the caustic alkalis, which convert it into oxide, but not by their carbonates. After the formation of the oxide in this way, the addition of sugar reduces it, and revives the silver. (Levol.) Silver chloride has been used in *syphilis*, *epilepsy*, *chronic dysentery* and *diarrhæa*, and other diseases in which silver nitrate has been given. The dose is from one to three grains or more (0.065–0.2 Gm.), four or five times a day.

Silver Citrate. *Argenti Citras*. *Itrol*. $\text{Ag}_3\text{C}_6\text{H}_5\text{O}_7$.—A dry, odorless powder, soluble with difficulty in water. This salt is recommended by Crédé as an antiseptic powder which may be dusted over a wound without producing irritation, or it may be injected subcutaneously into the surrounding tissue. It has been very highly recommended by O. Werler (*Derm. Zeit.*, Bd. cxi.) as intensely poisonous to the organism of *gonorrhæa*, and non-irritant to the urethral mucous membrane, and as further having the power of penetrating deeply into this membrane. The patient is to inject in the usual manner, four times a day, a solution of a strength varying from 1 in 4000 to 1 in 8000. As the itrol solution is immediately decomposed in contact with organic material, it is essential that the syringe and vessels used be kept absolutely clean. Even in *acute gonorrhæa* it is said that no burning or disagreeable sensations are caused. Werler also commends

it as a remedy in the treatment of chronic *cystitis*. Tilger and other surgeons have commended the remedy in the treatment of all forms of infected mucous membrane in saturated solution (1 in 3800).

Silver Fluoride. *Argenti Fluoridum*. AgF . Lazzaro claims for this preparation great antiseptic power, but there seems to be but little clinical or experimental evidence as to its value.

Silver Iodide. *Argenti Iodidum*. U. S. 1890. $\text{AgI} = 233.02$.—This salt may be readily prepared by adding a solution of potassium iodide to one of silver nitrate, and washing and drying the precipitate, which should be kept in dark amber-colored vials, protected from light. This iodide is said to have three allotropic forms and a point of maximum density at about 116°C . (240.8°F .) (see paper by G. F. Rodwell, in *Chem. News*, xx, 288; xxi, 14). The U. S. Pharmacopœia, 1890, describes it as "a heavy, amorphous, light yellowish powder, unaltered by light, if pure, but generally becoming somewhat greenish-yellow, and having neither odor nor taste. Insoluble in water, alcohol, diluted acids, or in solution of ammonium carbonate, but soluble in about 2500 parts of stronger ammonia water. It is also dissolved by an aqueous solution of potassium cyanide, and by a concentrated solution of potassium iodide, and the resulting solutions yield a black precipitate with hydrogen sulphide test-solution or ammonium sulphide test-solution. When heated to about 400°C . (752°F .), the salt melts to a dark red liquid, which, on cooling, congeals to a soft, yellow, slightly transparent mass. When mixed with ammonia water, it turns white, but regains its yellowish color upon being washed with water. If a small quantity of chlorine water be agitated with an excess of the salt, the filtrate acquires a bark blue color on the addition of starch test-solution. If 0.5 Gm. of the salt be digested for five minutes with 10 Cc. of a cold 15-per-cent. solution of ammonium carbonate, the filtrate, when supersaturated with nitric acid, should not be rendered more than faintly opalescent (absence of *chloride*). On digesting a portion of the salt—which has been found to be free from chloride, or from which the latter has been completely removed by repeated digestion with ammonium carbonate—for five minutes with 10 Cc. of ammonia water, and supersaturating the filtrate with nitric acid, only a slight opalescence, but no yellowish-white precipitate, should be produced (absence of *bromide*)." U. S. 1890. Silver iodide has been given in doses of one or two grains (0.065–0.13 Gm.) three times a day, in *epilepsy* and other chronic nervous diseases, but is devoid of value.

Silver Lactate. *Argenti Lactas*. *Actol*. $\text{AgC}_3\text{H}_5\text{O}_3$.—Silver lactate was introduced by Crédé as a surgical germicide. It is affirmed that its injection renders an infected wound rapidly aseptic without much irritation. It is soluble in 15 parts of water, and may be used in very strong, even saturated, solution. D. A. Tilger finds that the application of the pure powder to the curetted infected sore causes only moderate burning pain of short duration and acts most happily. (M. M. W., 1897.) Its therapeutic properties seem to be purely local, since E. Marx found that after injection of very large doses of it into animals it does not prevent the development of pathogenetic germs. It is almost certainly decomposed at the point of injection, but, unlike corrosive sublimate, it does not form an insoluble compound when brought in contact with tissues, and so is able to

find its way through these tissues. Fifteen grains (1 Gm.) of it have been given hypodermically without more serious symptoms than some burning pain at the point of injection. According to Marx, a remarkable rise of temperature follows the use of it in very large doses. Actol has been used to a considerable extent in dentistry, decayed or decaying pulp being washed with a solution of the strength of 1 in 2000 and then dusted with itrol.

Silver Orthophosphate. *Argenti Phosphas.* $\text{Ag}_3(\text{PO}_4)$.—This substance is prepared by dissolving silver in concentrated orthophosphoric acid; the vitreous mass which results while still melted is dissolved in water acidulated with phosphoric acid, yielding a permanent solution. Spretzka (*Rév. Méd. Pharm.*, 5, 292) asserts that it is a valuable remedy in *gonorrhœa*. The injection should contain 0.025 to 0.05 per cent. of the salt, increasing gradually to 0.25 or even 0.5 per cent.

Silver Phenolsulphonate. *Argenti Phenolsulphonas.* *Silver Sulphocarbolate.* *Silberol.* $\text{C}_6\text{H}_4(\text{OH})\text{SO}_3\text{Ag}$.—A crystalline powder containing 28 per cent. of metallic silver, soluble in water; proved to undergo spontaneous decomposition, but said to be more permanent than itrol. Originally introduced by Zanardi as having the antiseptic properties without the corrosive action of silver nitrate, *silberol* has been employed by various practitioners in the treatment of *gonorrhœa* and *ophthalmic inflammations*, and as a germicide in ocular surgery. It is asserted that a 2 per cent. solution is well borne as an antiseptic after operations upon the eye; also that when it is used as a substitute for silver nitrate *silberol* must be employed in twice as concentrated solution.

Silver Protalbin. *Largin.*—This is a compound of silver and protalbin, which occurs as a whitish powder, soluble in water to the extent of 10.5 per cent., freely soluble in glycerin, blood serum, and peptone solution. Not precipitated by chlorides nor yet by albumin, and containing 11.1 per cent. of silver. In brown bottles it keeps unchanged indefinitely. Owing to the fact that it does not coagulate albumin its penetrating powers when brought in contact with the mucous membrane are very great, and it is claimed by many German clinicians that as a specific germicide in the treatment of *gonorrhœal affections* it is pre-eminent. In male *gonorrhœa* the strength of the injection should be one-fourth of one per cent., gradually increased up to two per cent. After the disappearance of the gonococci the treatment should be continued with the aid of astringents, and finally injections should be made with one-fourth to one-half per cent. of *largin*. In women the parts may be irrigated with from a one-half to one per cent. solution, after which a 5 per cent. *largin* bougie may be held in position by a cotton plug for fifteen minutes and the part again irrigated with a 5 per cent. solution of *largin*. This should be repeated daily for one week; subsequently every second or third day only. *Largin* is also largely used in the treatment of infectious *conjunctivitis* and *catarrhal corneal ulcers* in the form of gelatin tablets containing one per cent.

Silver Quinaseptolate. *Argenti Quinaseptolas.* *Argentol.* $\text{C}_6\text{H}_5\text{N.OHSO}_3\text{Ag}$.—This substance is a yellow powder, sparingly soluble in water, which was introduced into medicine by Cr  d   on account of its readily splitting up into

oxyquinoline and metallic silver. Both septic matters and intestinal juices are said to produce this change. It has been employed either as a dusting powder or in the form of spray, or injection, 1 in 300 to 1000, in *chancres*, *gonorrhœas*, and various other surgical infections. C. Cipriani asserts that it is a valuable intestinal antiseptic of which 15 grains (1 Gm.) may be given safely in the twenty-four hours if necessary. It is said also to be an active non-irritant antiseptic with marked hemostatic properties.

Silver, Soluble. *Argentum Solubile.* *Argentum Colloidale.* *Collargol.* *Soluble Silver.* *Colloidal Silver.*—Several allotropic modifications of silver were discovered by Carey Lea in 1891. One of these has been introduced into medicine. "Soluble Silver," so called, can be prepared by taking a mixture of 30 Gm. ferrous sulphate dissolved in 100 Cc. of water and 36 Gm. of crystallized sodium citrate dissolved in 140 Cc. of water and pouring this mixture with stirring into 100 Cc. of a 10 per cent. silver nitrate solution. After allowing the precipitate to settle, the supernatant liquid is poured off, the precipitate dissolved in water, and again precipitated with absolute alcohol. When dried, the colloidal silver is a bluish or green-colored mass, which dissolves in water with a deep red color, but is precipitated from its solution by the addition of salt solutions. It contains 97.2 per cent. silver. Chassevant and Posternak find the collargol of commerce does not contain more than eighty-seven per cent. of silver, the rest being albuminous matter. (*C. R. S. B.*, 1903, lv.) Used in the preparation of *Unguentum Cr  d  *. Soluble silver was originally employed by Cr  d   as a non-poisonous germicide, to be used as internal medication in various affections such as septicæmia, diphtheria, tuberculosis. At first he administered it by inunctions, forty-five grains (3 Gm.) at one time for the adult, but later gave eighty grains to five drachms (5.2–20 Gm.) of the 1 per cent. solution hypodermically or intravenously. The harmlessness of these intravenous injections has been confirmed by M  ller, who also affirms that in septic diseases collargol may be given with as much trust as antitoxin in diphtheria. The value of the remedy is, however, very doubtful; the experiments of George Brunner have shown that collargol is precipitated by gelatin bouillon; that it is not soluble in blood serum, although it remains dissolved if the solution of it be mixed with the serum; that the germicidal properties of it are very feeble, twelve hours contact with the one per cent. solution of it being required to kill most pathogenetic bacteria; that when given subcutaneously or intravenously it has no apparent effect upon animals, and that granules of silver can be found later at the places of injection,—finally, that whether given with infectious matter or injected after such material, it has no influence over the processes of the resulting infection or upon the bactericidal power of the blood. The chills and other constitutional disturbances which were formerly produced (but at present are not) by the intravenous injections of collargol were probably due to the presence of impurities in the solutions used, and the whole drift of evidence is to show that collargol probably never circulates in the blood, and that it is physiologically inert.

Silver Thiohydrocarburo-sulphonate. *Argenti Thiohydrocarburo-sulphonas.* *Ichthargan.* This compound of ichthylol-sulphonic acid and silver is a brown amorphous stable powder, freely

soluble in water, glycerin and diluted alcohol, insoluble in alcohol, ether, and chloroform. Its aqueous solution blackens with exposure to light, and in concentrated solution it is precipitated by sodium chloride and by albumin, the albuminous precipitate being redissolved by an excess of albumin. It is said to contain about 30 per cent. of silver and 15 per cent. of sulphur, and to be very much more destructive to gonorrhœal, pyogenic, diphtheritic, and typhoid germs than is either colloidal silver or protargol. In gonorrhœa and all syphilitic ulcerations, *ozæna*, infected phlegmons, infected wounds, diseases of the throat and nose, eczema, acute and chronic conjunctivitis, and other local diseases it is largely used.

The strength of the ichthargan solution varies in gonorrhœa from 1 in 500 to 1 in 3000 for injections; from 1 in 2000 to 1 in 5000 for irrigation; 1 to 3 per cent. in instillations. In the gonorrhœa of women most excellent results are said to follow packing the vagina with tampons saturated with a solution of 1 to 5 parts of ichthargan, 5 of water, and 100 of glycerin; a 5 to 10 per cent. ointment may also be employed. In chanoroids the powder of ichthargan, full strength or diluted, may be used. In trachoma, gonorrhœal, and other infective conjunctivitis, the 1 to 3 per cent. solution may be applied with a brush; 1 in 1000 used as a wash. In eczema, ulcerations, phlegmons, and in lymphangitis, the ointment varying from 1 to 15 per cent. is advised, well rubbed into the adjacent healthy skin, previously thoroughly cleansed, and also applied directly to the affected surface, if it be exposed. Ichthargan has also been administered internally with asserted excellent results for the relief of gastritis and especially of gastric ulcer. Dose, one-twentieth to one-eighth of a grain (0.003–0.008 Gm.) in half a fluidounce (15 Cc.) of water, on an empty stomach. Intravenously, ichthargan has been used experimentally in various septic diseases, such as septic endocarditis, septicæmia, etc. It is stated that injections of 0.01 to 0.02 Gm. per kilo (one-sixth to one-third grain per two and a half pounds) may be given without risk. At present there is no sufficient evidence of the value of this treatment.

Silver Vitellin. *Argentio Vitellin.* *Argyrol.* This substance is said to be produced by extracting gliadin from wheat, treating it in an autoclave with dilute hydrochloric acid under pressure, and obtaining thereby a white granular precipitate which is said to be of the nature of a vitellin, and then combining this with silver, the resulting product being a dark brown powder containing 30 per cent. of metal. Silver vitellin is so soluble that one ounce may be dissolved in three drachms of water. The solution does not precipitate albumin or sodium chloride, and has therefore very marked penetrative properties. It has been used in gonorrhœa, and found unirritating and effective in a one per cent. solution. The 50 per cent. solution is stated to be equal in germicidal powers to the 25 per cent. solution of silver nitrate, but according to Marshall and Neave (*J. A. M. A.*, Sept. 15, 1906) it has no bactericidal properties.

In injections the strength of the solution should usually be one to five per cent., although on occasion stronger solutions are usually well borne. For irrigation, solutions of the strength of 1 in 2000 to 1 in 500 are employed. Even the stronger solutions are said not to produce unpleasant symptoms.

Simaruba.—Under this name the U. S. P. formerly recognized the bark of the root of *S. amara*, Aublet (*S. officinalis*, DC., *Quassia Simaruba*, L.). *Ecorce de simarouba*, Fr. *Simarubarinde*, *Ruhrinde*, G. *Corteccia di Simaruba*, It. *Corteza de Simaruba*, Sp. (Fam. Simarubaceæ.) This is a tree of considerable height, having alternate branches, with a bark which in the old tree is black and somewhat furrowed, in the young is smooth, gray, and marked here and there with broad yellow spots.

It is a native of French Guiana and the Islands of Dominica, Martinique, St. Lucia, St. Vincent and Barbados, in the West Indies. A closely related species, having, however, diocious instead of monœcious flowers, flourishes in Jamaica, San Domingo, Bahama Islands, Panama, and Guatemala, extending even to Florida. It is called in Jamaica *mountain damson*, and is known to botanists as *S. glauca*, DC. (*Quassia glauca*, Spreng., *S. officinalis*, Macf., not DC.). The two species have probably identical medicinal properties. The bark of the root is the part employed, the wood being nearly tasteless and inert. The middle bark contains much resin. A decoction of the bark and leaves of *S. versicolor*, St.-Hil. (*Cortex Paraibæ*), is employed in Brazil as an antidote for snakebites and in the treatment of syphilis and tape worm; the powder is used against vermin.

Simaruba bark is in long pieces, some inches in breadth, folded lengthwise, light, flexible, tenacious, very fibrous, externally of a light brownish-yellow color, rough, warty, and marked with transverse ridges, internally of a pale yellow. It is without odor, and of a bitter taste. It readily imparts its virtues, at ordinary temperatures, to water and alcohol. The infusion is at least equally bitter with the decoction, which becomes turbid as it cools. Its constituents, according to Morin, are a bitter principle identical with quassin, $C_{10}H_{12}O_8$, a resinous matter, a volatile oil having the odor of benzoin, malic acid, gallic acid in very minute proportion, an ammoniacal salt, calcium malate and oxalate, some mineral salts, ferric oxide, silica, ulmin, and lignin. Simaruba possesses the same tonic properties as other simple bitters. In large doses it is said to purge and vomit. On account of its difficult pulverization, it is seldom given in substance. The best mode of administration is by infusion. The dose is from twenty grains to a drachm (1.3–3.9 Gm.).

Simulo.—The dried fruit of one of the *Capparis* coriariaceæ has been highly recommended by reputable clinicians as a palliative in epilepsy; also in chorea. (See *T. G.*, 1888, 1889; and *Th. M.*, Aug. 1888.)

Sirolin.—A preparation of beech tar containing a large proportion of guaiacol. It has been used in the same class of pulmonary diseases as creosote. The adult dose is one fluidrachm (3.75 Cc.).

Sisymbrium. *Sisymbrium officinale* (L.), Scop. (*Erysimum officinale*, L.) Hedge Mustard. *Herbe aux chantes*, Tortelle, Fr. *Wildersenf*, *Hederich*, G. (Fam. Cruciferae.)—This annual, growing in Europe and the United States, is said to be diuretic and expectorant, and has been recommended in chronic coughs, hoarseness, and ulceration of the mouth and fauces. The juice of the plant may be used mixed with honey or sugar, or the seeds may be taken in substance. *Sisymbrium Sophia*, L. (*Sophia Sophia* (L.), Brit.), or the *flaw weed*, was formerly official. It is of a pungent odor when rubbed, and of an acrid,

biting taste. W. Zopf attributes its poisonous qualities to a volatile alkaloid. (*Zeit. f. Nat. Pharm. Central.*, 1894, 494.) The herb has been used externally in indolent ulcers, and the seeds internally in worms, calculous complaints, etc. *Diplotaxis muralis*, DC. (*Sisymbrium murale*, L.), has been used in France in *scurvy*, *scrofula*, and other cachectic affections, especially associated, in the form of a syrup, with potassium iodide. (*Ann. Thér.*, 1863, 126.) Grazing sheep are said to be killed in Southern France by feeding on *Diplotaxis tenuifolia*, DC., and human poisoning has occurred. George Heyl has separated a toxic and apparently uncrystallizable alkaloid (*Ap. Ztg.*, May 30, 1900).

Sium.—*Sium cicutefolium*, Gmel. (*Sium latifolium* of American authors, not of Linné), which grows in British America and the United States, particularly along the water courses of the valleys of the Pacific slope, and is the *hemlock water parsnip* of this country, is positively asserted to be poisonous. A. R. Porter and N. Rogers (*A. J. P.*, 1876, 348, 483) found in it an active resinous body, toxic to animals. *S. Sisarum*, L., or *skirret*, a plant of Chinese origin, cultivated in Europe, has a sweetish, somewhat aromatic root; it is employed as a salad, and is supposed to be a useful diet in chest complaints.

Skimmia. *Skimmia japonica*, Thunb. *Miramshikimi*.—From this rutaceous plant, which is cultivated in its native country on account of the beauty of its flowers and berries, Eykman separated a glucoside, *skimmia*, and a decomposition product, *skimmetin*. (*Abandl. d. Tokyo Daigaku.*, No. 10, Tokyo, 1883.) J. Honda (*A. E. P. P.*, Oct. 1904), however, finds that the activity of the plant depends upon the presence of the crystalline alkaloid, *skimmianin*. It is a muscle poison, producing no primary excitement in the muscle, but an increasing paralysis, the influence of the alkaloid extending to involuntary muscles, such as the heart, so that in mammals arterial pressure is progressively decreased.

Skin Varnishes.—Unna has devised a series of preparations for forming thin coverings on the skin. We reproduce the most important formulas.

Bassorin Varnish.—The pure bassorin basis is obtained, according to Elliot, by passing tragacanth mucilage (15 to 100) through a filter heated by steam, evaporating, and mixing with glycerin. A similar basis may be prepared by stirring 5 parts powdered salep with 95 parts cold water until a smooth mucilage is obtained, then heating for half an hour on the steam bath. The salep basis contains less bassorin, but more starch.

Casein Varnish.—The casein obtained by coagulating skimmed milk with rennet at a temperature of from 35° to 40° C. (95°–104° F.) is washed and dried until it forms a yellowish-white sandy powder soluble in alkaline solution. In preparing this varnish the casein is dissolved by means of borax. For 20 parts casein 2.5 parts borax and 77.5 parts water furnish a rapidly drying uniform covering material. The alkaline characters of the borax are masked by the casein. Admixtures of heavy pulverulent substances readily settle out of this basis, and it is requisite to distribute them by shaking. A varnish of casein and glycerin is prepared by dissolving the casein in 3 or 3.5 parts of ammonia water, adding a quantity of glycerin equal in weight to the casein, and heating to drive off the ammonia. The resulting mass mixed with twice its weight of boiling water gives an excellent permanent emulsion.

Amber Varnish.—Made by dissolving a mixture of amber and turpentine in alcohol. It must not be used as a vehicle for the application of zinc oxide.

Castor Oil and Shellac Varnish.—With 1 part shellac, 1½ parts castor oil, and 3 parts alcohol, a varnish is obtained which forms a good flexible covering easily removed by alcohol.

Canada Balsam and Collodion Varnish.—Sixteen parts collodion with 1 part Canada balsam furnish a material suitable for the application of pyrogallol, and it can be easily removed by alcohol.

Castor Oil and Collodion Varnish.—Eight parts collodion and 1 part castor oil.

Lead Ricinoleate Varnish.—One part lead oxide heated with 1½ parts castor oil to saponification, and mixed with 2 parts absolute alcohol, gives a good skin varnish.

Chrysarobin Amber Varnish.—One part chrysarobin and 20 parts amber dissolved in turpentine.

Pyrogallol Shellac Varnish.—One part pyrogallol, 1 part castor oil, 5 parts shellac, and 15 parts absolute alcohol.

Salicylic Acid, Canada Balsam, and Collodion Varnish.—One part Canada balsam, 10 parts collodion, and 3 parts salicylic acid.

Zinc Oxide, Castor Oil, and Collodion Varnish.—Two parts zinc oxide, 2 parts castor oil, and 16 parts collodion.

Zinc and Lead Ricinoleate Varnish.—Five parts lead ricinoleate, 8 parts zinc oxide, 8 parts absolute alcohol, and, lastly, 1 part each of collodion and ether.

Ichthyol Borax Casein Varnish.—Five parts sodium ichthyolate and 15 parts borax casein varnish.

Sulphur Glycerin Casein Varnish.—Five parts sulphur and 15 parts glycerin and casein varnish.

Zinc Oxide Salepbassorin Varnish.—Two parts zinc oxide and 18 parts salepbassorin varnish.

Zinc Ichthyol Tragacanth Bassorin Varnish.—One part sodium ichthyolate, 2 parts zinc oxide, and 17 parts tragacanth bassorin varnish.

Smalt. *Smalts.* *Azure.*—When the impure cobalt oxide, obtained by roasting the native arsenide of that metal, is heated with sand and potassium hydroxide, the mixture melts, and a beautiful blue glass results, which, when reduced to powder, forms smalt or azure. It is used chiefly in painting, and for coloring glass and porcelain.

Sodium and Silver Thiosulphate. *Sodii et Argenti Thiosulphas.*—This double salt may be prepared by dissolving freshly precipitated silver oxide in a solution of sodium thiosulphate and evaporating the solution. It is in the form of minute crystals of the formula $2\text{Na}_2\text{S}_2\text{O}_3 + \text{Ag}_2\text{S}_2\text{O}_3$, very soluble in water, but insoluble in alcohol, and possessing a sweet taste. Its solution, protected from the light, undergoes no change, and, when quite pure, does not discolor the skin or linen. Delieux states that this salt acts locally like silver nitrate, but more mildly: for *gonorrhœa*, one or two parts in two hundred of water.

Sodium Boro-Salicylate. *Sodii Boro-salicylas.* This is made by heating 125 parts of boric acid, 320 parts of sodium salicylate, and 700 parts of water in a flask until a syrupy liquid is produced; this solidifies on cooling, yielding a white product. It dissolves in water. It is used as an antiseptic and preservative.

Sodium Caseinate. *Sodii Caseinas.* *Nutrose.* *Casein-natrium*, G.—A combination of casein and

sodium hydroxide, just enough of the alkali being used to dissolve the freshly precipitated casein. The solution is evaporated *in vacuo*, the dry residue powdered, thoroughly washed with alcohol, and then with ether and dried. A white amorphous powder, with little odor or taste, insoluble in alcohol and ether, slightly so in cold water but readily soluble in hot water. It is considered to be a valuable food in intestinal and digestive disturbances, also in *anæmia* and *scrofula*.

Sodium Eosinate (*Tetrabromo-fluorescein-sodium*). $C_{20}H_6O_6Br_4Na_2$.—A brownish-red powder which freely dissolves in water and alcohol, containing about 40 per cent. of bromine. It has been tried in *epilepsy* by Bourneville and Chapotin, who found that it caused such unpleasant secondary symptoms that its use had to be discontinued.

Sodium Ethylate. *Sodii Ethylas*. *Ethylate of Sodium*. *Caustic Alcohol*. C_2H_5ONa .—This preparation was introduced by B. W. Richardson of England, as a caustic. He makes it by adding sodium in small pieces gradually to absolute alcohol, kept at a temperature of $10^\circ C.$ ($50^\circ F.$); hydrogen is evolved, and when, owing to the formation of the ethylate, the reaction slackens, the liquid is to be carefully heated to $37.7^\circ C.$ ($100^\circ F.$). Sodium is then cautiously added until the reaction ceases; the liquid is cooled to $10^\circ C.$ ($50^\circ F.$), and the same quantity of absolute alcohol added as was used in the beginning. (P. J., 1878, 485.) Sodium ethylate is a white powder, frequently having a brownish tinge, dissolving in water with a hissing sound, having the property of splitting into alcohol and sodium hydroxide upon contact with even a small quantity of water or moist living tissue:

Sodium ethylate does not appear to be of any value as an internal remedy. When, however, it comes in contact with moist tissue, owing to the liberation of its sodium, it acts as a very speedy and powerful caustic. It should always be used in alcoholic solution, and applied by means of a glass rod. It is said to cause very little pain, and has been specially employed for the destruction of *navi*. (L. L., Nov. 1878.) Richardson states that it should always be kept in glass-stoppered bottles, in a cold place, as he has known it to explode when placed in warm situations. Gamberini and Monari (R. T., 1892) assert that the 20 per cent. liniment made with olive oil, well rubbed in daily, will usually cure *psoriasis* in twenty days, and that the 10 per cent. aqueous solution is very valuable in the treatment of *lupus erythematosus*, applied after curetting.

Sodium Formate. *Sodii Formas*. *Ameisensäures Natrium*, G. $HCO_2Na + H_2O$.—Prepared by neutralizing formic acid with sodium carbonate. It occurs in colorless rhombic prisms, which are inodorous, and have a saline, bitter taste. Sodium formate is very deliquescent and dissolves freely in water.

Sodium Glycerophosphate. *Sodii Glycerophosphas*. $C_3H_7O_3PO_3Na_2 + H_2O$.—Made by neutralizing glycerophosphoric acid with sodium carbonate. Commercially it occurs as a 75 per cent. solution having a light yellow color. It is used as a nerve and tonic in doses of from three to five grains (0.2–0.32 Gm.), and in the treatment of deficient nerve nutrition, *neurasthenia*, convalescence from *influenza*, *exophthalmic goitre*, *lumbago*, and Addison's disease, it may be administered, in hypodermic injection, in doses of three to four grains (0.2–0.26 Gm.) daily.

Sodium Lygosinate is said to be obtained from *diorthocoumariketone*, which was introduced into medicine under the name of *lygosin*, a ruby-red salt readily soluble in water. According to the experiments of Fabinyi (S. Jb., Bd. 271, 179), this substance acts antipyretically upon the rabbit and has very feeble germicidal powers.

Sodium Methylarsenate. *Sodii Methylarsenas*.—*Arrhenal*, $OAsCH_3O_2Na_2 + 5H_2O$, is obtained by the action of methyl iodide upon sodium arsenite in the presence of excess of alkali. It occurs in colorless crystals, which are easily soluble in water. This substance contains about 27.3 per cent. of metallic arsenic, corresponding to 36 per cent. of arsenic trioxide, but is said to be non-poisonous in doses of 3 grains (0.2 Gm.), it should nevertheless be given with caution. It has been used in *tuberculosis*, *malaria*, *anæmia*, and other conditions for which arsenic is employed, but is probably of very little therapeutic value.

Sodium Naphthol. *Naphthol Sodium*.— β -*Naphthol sodium* (*microcidine*), a white powder easily soluble in water, used as a non-caustic, non-poisonous antiseptic, said to be much stronger than phenol.

Sodium Nitroferrocyanide. *Sodium Nitroprusside*. *Sodii Nitroferrocyanidum*. $Na_2Fe(CN)_5NO$.—This is one of the interesting series of salts, discovered by Playfair, called *nitroprussides*, which are produced, for the most part, by saturating *nitroferrocyanic acid*, formed by the action of nitric acid on potassium ferrocyanide, with different bases. The sodium salt is best obtained by the process of A. Overbeck, as follows: Dissolve four parts of powdered potassium ferrocyanide, contained in a flask, in five and a half parts of commercial nitric acid, diluted with an equal weight of water. After the action is completed, which generally occupies about ten minutes and is accompanied by a copious evolution of gases, heat the resulting coffee-brown liquid in a water bath, until a drop of it gives a dingy green instead of a blue precipitate with a solution of ferrous sulphate. Then allow the liquid to cool; whereupon the larger part of the potassium nitrate generated will be deposited in crystals. Pour off the green mother liquor from these, and separate the remaining potassium nitrate by repeated concentrations. Next, neutralize the liquid, while heated in a water bath, with sodium carbonate, taking care to add the carbonate so long as a pure blue precipitate is produced. Lastly, filter the solution, and set it aside for the formation of crystals, which must be washed with water, and dried between blotting paper. The salt is in the form of large, ruby-colored, prismatic crystals, resembling those of potassium ferriocyanide. It is soluble in two and a half parts of cold water, and in less quantity of hot water. Its solution, exposed to sunshine, is decomposed, with evolution of nitric oxide gas, and deposition of Prussian blue, at the same time acquiring a green color. Sodium nitroprusside, as well as the other soluble nitroprussides, is a most delicate test for alkaline sulphides, with which it strikes a violet color.

Sodium Oleate. *Sodii Oleas*. *Eunatrol*.—Sodium oleate may be made by dissolving 10 parts of sodium hydroxide in alcohol and adding the solution to 100 parts of oleic acid and carefully evaporating the soap which is formed to dryness. It is a whitish mass or a white powder, dissolving freely in water and alcohol. According to F. Blum (*Der*

ärztel. Praktiker, 1897), it has a very powerful action upon the liver, making it very useful in cases of gall stones and chronic hepatic torpor. Dose, from thirty to eighty grains (2-5.2 Gm.) daily in capsules.

Sodium Paracresotate. *Sodii Paracresotat.* $C_6H_5(OH)CH_2CO_2Na$.—This salt is recommended as an internal antiseptic; it is prepared by heating creosol-sodium with carbonic acid, and occurs in colorless and odorless crystals of bitter taste, insoluble in cold water, but soluble in warm water. In the diarrhoea of children it is given in doses of from five to forty-five grains (0.32-3.0 Gm.).

Sodium Peroxide. *Sodii Peroxidum.*—Vernon Harcourt has shown that this peroxide is readily decomposed by water, with production of sodium hydroxide, oxygen, and hydrogen dioxide. The reaction takes place in the cold, and the yield of oxygen is about that of the theoretical requirement, viz., one atom of oxygen for every molecule of sodium peroxide decomposed. Unna's sodium peroxide soap consists of 3 parts of liquid petrolatum, 7 parts of completely dried soap, and 2.5, 5 or 10 per cent. of powdered sodium peroxide. It is adapted to impart to a pale and excessively cornified facial skin pitted with comedones a healthy rosy color and a softened surface. It has also been used in *rosacea pustulosa* with asserted benefit.

Sodium Phenolsulpho-ricinate. *Sodii Phenolsulpho-ricinas* (25 per cent.).—This phenol compound has been highly recommended as a local application in laryngeal tuberculosis and papilloma; also in *ozæna*. In the latter disease the pituitary membrane and the nasal ducts are first cleansed and subjected to vigorous daily frictions with the aid of a sound padded with wadding steeped in a solution of sodium phenol-sulpho-ricinate (1 to 2 or 3 parts of water.)

Sodium Selenite. *Sodii Selenis.* Na_2SeO_3 .—A white powder which freely dissolves in water. The aqueous 2 per cent. solution of sodium selenite stains bacteria red by the precipitate of metallic selenium, and has been highly recommended for the purposes of microscopic staining.

Sodium Silicate. *Sodii Silicas.* *Soluble Glass.* Na_2SiO_3 , or frequently $Na_2Si_4O_9$.—Sodium silicate is made by fusing one part of silica, fine sand, or powdered flint, and two parts of dried sodium carbonate, mixed in powder, in an earthenware crucible, and pouring out the fused mass on a stone slab to cool. This is pulverized, and treated with boiling water, to dissolve the soluble part. The solution is filtered and concentrated, so as to form crystals on cooling. These are then purified by dissolving them in water heated to 37.7° C. (100° F.), filtering the solution, and concentrating it so that it may recrystallize. The commercial solution of sodium silicate usually contains about 20 per cent. of silica and 10 per cent. of soda. It is employed in fixing fresco colors by the process of stereochromy, as a cement in the manufacture of artificial stone, and as an addition to soaps, constituting the so-called *silicate soaps*. As long ago as 1872, Dumas, Rabuteau, Papillon, Picot, Champouillon, and other French writers asserted that sodium silicate was an antiseptic, valuable in the treatment of chronic urethritis, vaginitis, etc., and P. Coreman has shown that pathogenetic germs are killed in one hour by its solution. (*La Presse Méd.*, 1897.) R. Löwenhaupt, however, asserts that when pure it is not antiseptic, any powers which it may seem to have

being dependent upon the presence of free alkali in it, and certainly as a practical remedy it has failed to come into use.

Under the name of *Liquor Sodii Silicatis* the U. S. Pharm. 1890 formerly recognized the solution of sodium silicate, describing it as "a semi-transparent, almost colorless, or yellowish, or pale greenish-yellow, viscid liquid, odorless, having a sharp, saline, and alkaline taste, and an alkaline reaction. Specific gravity, 1.300 to 1.400 at 15° C. (59° F.). A drop of the Solution, when held in a non-luminous flame, imparts to it an intensely yellow color. If a portion of the Solution, largely diluted with water, be supersaturated with nitric acid, a gelatinous or pulverulent, white precipitate of silicic hydrate will be produced." The solution is used solely in the preparation of mechanical dressings by the surgeon.

Sodium Silico-Fluoride. *Sodii Silico-fluoridum.* Na_2SiF_6 .—When gaseous SiF_4 , generated by the action of sulphuric acid upon fluorspar in the presence of broken glass, is passed into water, hydrogen silico-fluoride, H_2SiF_6 , is formed. This acid, when neutralized by sodium hydroxide or carbonate, will yield the sodium salt. It is difficultly soluble in water. It is asserted for the *silico-fluoride of sodium* that its solution, *salufer*, is practically non-toxic and powerfully antiseptic. The powder is a strong irritant or a mild caustic. The solution affects steel instruments. Bokenham, in experiments upon bacteria, found that in order to kill them it was necessary for the solution to be at least as strong as one to seven hundred and fifty parts, and that the drug has toxic properties, 0.05 Gm. of it causing prolonged nausea, great slowing of pulse, and reduction of arterial pressure.

Sodium Stearate. *Sodii Stearas.* $NaC_{16}H_{33}O_2$.—The pencils of this substance, which have been recommended by T. G. Unna for use in *syccosis* and other parasitic skin diseases, are made as follows: Sodium stearate, 6 Gm. (90 gr.); glycerin, 2.5 Gm. (30 min.); alcohol, sufficient to make 100 Gm. (4 fl. oz.). The affected part should be rubbed with the pencil five or six times daily.

Sodium Succinate. *Sodii Succinas.* $Na_2C_4H_4O_4 + 6H_2O$.—White crystals freely dissolving in water. Sodium succinate has been highly commended by Ch. F. Hope for *catarrhal jaundice*. Dose, fifteen to twenty grains (1-1.3 Gm.) every three or four hours.

Sodium Sulphobenzoate. *Sodii Benzosulphonas.* *Sodium benzosulphonate.* $C_6H_4(NaSO_3)COONa$.—Heckel (*C. R. A. S.* cv. 896) asserts that sodium sulphobenzoate is a non-poisonous antiseptic, superior to phenol, and equal to mercurial solution in the antiseptic treatment of wounds; strength of solution about fifty grains in a quart.

Sodium Sulphomethylate. *Sodii Methylsulphonas.* *Sodium methylsulphonate.* $CH_3(OH)SO_3Na + H_2O$.—According to Rabuteau, this salt in 240 grain (15.5 Gm.) doses produces catharsis without cramp. (*A. J. P.*, 1880, 220.)

Sodium Sulphoricinoleate. *Oleite.*—This substance may be prepared from castor oil by treating it with sulphuric acid at a low temperature, when a compound of sulphuric and ricinoleic acids is formed. The free sulphuric acid being removed by washing, and any unchanged oil by ether, the resulting sulphoricinoleic acid is then neutralized by sodium hydroxide, the finished product being a transparent, jelly-like liquid, with little odor, having an acrid taste, and soluble in water, alcohol, chloroform, and essential oils.

The solvent powers of oleites upon medicinal substances are said to be extraordinary, there being only a few which will not yield to it to a greater or less degree. According to the experiments of Fred. B. Kilmer (*Proc. A. Ph. A.*, 1890; *P. J.*, xx, 1890), its action upon mucous membranes, healthy and diseased skin, cuts, burns, etc., is highly soothing, and it may be taken internally or freely absorbed through the skin without danger. It would appear, therefore, to afford an excellent basis for ointments; but as productions made with it are very sticky, and often liable to harden, it is commonly best used by rubbing the substance with oleite, and then adding 50 per cent. of fatty base.

Phenol sulphuricinate is made by adding pure phenol to sulphuric acid; it is a yellowish liquid employed for tuberculous affections. *Phenol and sodium ricinate*—20 per cent. of phenol and 80 per cent. of sodium sulphuricinate—is used as an antiseptic, and in 20 per cent. aqueous solution to destroy diphtheritic membrane.

Sodium Sulphosalicylate. *Sodii Salicylsulphonas.* $\text{C}_6\text{H}_5(\text{OH})\text{COOH}$
 SO_3Na^+ *Sodium Salicylsulphonate.*—*Salicylsulphonic acid*, made by acting on salicylic acid with sulphuric acid, is partly neutralized with sodium carbonate. It occurs as a white crystalline powder, soluble in twenty-five parts of water, insoluble in alcohol and ether. It is used as a substitute for sodium salicylate.

Sodium Sulphovinate. *Sodium Ethylsulphate.* $\text{C}_2\text{H}_5(\text{OH})\text{SO}_3\text{Na} + \text{H}_2\text{O}$.—This salt occurs as a white granular powder or in hexagonal tabular crystals, according to the method of its preparation. Its taste is cooling and rather aromatic, nearly destitute of bitterness. It is very deliquescent, and is soluble in 0.7 part of water.

When sulphuric acid is added to alcohol the temperature rises at once, and a certain proportion of sulphovinic acid is formed, but, as water is at the same time developed, the reaction is soon arrested by the dilution of the mass. The first practical method of overcoming the difficulty was afforded by the process of Limousin. Nineteen and a half ounces (avoirdupois) each of pure sulphuric acid, sp. gr. 1.715 and of concentrated alcohol, about 96°, are slowly introduced by means of two funnels (one for the alcohol and the other for the acid) into a third funnel arranged in a flask plunged into a freezing mixture or kept in a current of cold water, the flow of the two liquids into the flask being so regulated as to keep the alcohol in excess. The mixture is kept for four to five days at a temperature of from 20° C. (68° F.) to 25° C. (77° F.), then diluted with from nine to ten pints of distilled water, and carefully saturated with somewhat less than forty-eight ounces of pure barium carbonate in solution. When the point of saturation has been attained, the liquid is left to deposit the barium sulphate, and afterwards filtered. The solution of barium sulphovinate so obtained is saturated with between twenty-seven and twenty-nine ounces of pure sodium carbonate dissolved in four litres of distilled water. When no more precipitate is formed by the addition of the alkaline solution, and the liquid is neutral to test paper, the transformation of the barium sulphovinate into sodium sulphovinate is complete. The liquor, decanted and filtered, is evaporated in a water bath until it has the sp. gr. 1.33, and left to crystallize. The drained crystals are dried in an oven.

Various other processes have been proposed. T. L. Phipson (*Chem. News*, 1874, 221; also *A. J. P.*, xlvii, 27) mixes small quantities of concentrated sulphuric acid and alcohol; keeps for from eight to ten hours at a temperature of 37.7° C. (100° F.); cools; adds the mixture drop by drop to about twenty times its volume of cold distilled water, cooling at times; adds chalk to this solution until effervescence ceases; filters, heats the filtrate with a little calcium carbonate for about half an hour; filters while warm, and evaporates at a heat not exceeding 37.7° C. (100° F.) till a permanent saline crust forms on the surface, and sets aside to crystallize. The calcium sulphovinate thus formed is in large brilliant plates, readily converted into a corresponding salt of sodium. Dubois modifies (*J. P. C.*, 1875, 44) the method of Limousin by saturating the first mixture, containing sulphovinic acid, with a concentrated solution of sodium hydroxide in strong alcohol, keeping the mixture constantly cold, and adding the alkaline mixture by small portions. The filtered liquid is evaporated as in the method of Phipson, or, preferably, Dubois precipitates the mixture, diluted with strong alcohol, with sodium carbonate. Limousin's process, as thus modified, appears to be preferable to that of Charles Rice, detailed in *A. J. P.*, 1873, 60. Sodium sulphovinate is said to be a mild although active cathartic. According to Rabuteau, five drachms (19.4 Gm.) of it dissolved in three glasses of water will generally produce in the adult four or five liquid stools without pain. The dose for children is from two to three drachms (7.7–11.6 Gm.). The pleasantness of its taste and action would render it a favorite purgative were it not for its high price and the difficulty of preserving it, all of the sulphovinates having a great tendency on exposure to the air to break up into alcohol and a salt of sulphuric acid.

Sodium Tartrate. *Sodii Tartras.* $\text{Na}_2\text{C}_4\text{H}_4\text{O}_6 \cdot 2\text{H}_2\text{O}$.—This salt, in crystals, has been recommended by Delieux as an agreeable purgative, almost without taste, and acting with a power equal to that of the magnesium sulphate in the dose of ten drachms. The *soda powders*, so much used in the United States, form an extemporaneous sodium tartrate, somewhat aerated with carbon dioxide. A solution of sodium tartrate has been used as a substitute for solution of magnesium citrate. It may be made by dissolving six drachms of tartaric acid in two fluidounces of water, and seven and a half drachms of sodium bicarbonate in seven fluidounces of water, mixing the solutions gradually and filtering; the filtrate should be poured into a strong twelve fluidounce bottle and two fluidounces of lemon syrup added slowly, so that it will sink to the bottom of the bottle without mixing very much with the solution; eighty grains of tartaric acid are to be added without agitating the bottle, which is to be corked at once securely and set aside in a cool place. The bottle is to be shaken just before the contents are administered.

Sodium Tellurite. Na_2TeO_3 .—*Sodium tellurite* is a white powder sparingly soluble in water. The aqueous 2 per cent. solution of sodium tellurite stains bacteria black by the precipitate of *metallic tellurium*, and has been highly recommended for the purposes of microscopic staining.

Sodium Tetraborate. *Sodii Tetraboras. Antipyonin.*—Sodium tetraborate is made by boiling borax and boric acid in water. It occurs as a fine, white powder, greasy to the touch, freely soluble

in water. This salt is non-poisonous, devoid of caustic action, and markedly antiseptic. It is probably therapeutically equivalent to borax, but has been especially recommended in a 2 to 50 per cent. solution, or blown in as a powder, by Jaenicke and by Kafemann in *acute and chronic otorrhœa*. Roland attributes extraordinary effects to its insufflation in *keratitis, conjunctivitis*, and other inflammatory eye conditions.

Sodium Valerate. *Sodii Valerianas.* *Sodii Valeras.*—This salt was dismissed from the U. S. Pharmacopœia in 1870, and from the British Pharmacopœia in 1898. The British process for its preparation was as follows: "Take of Amylic Alcohol four fluid ounces [Imperial measure]; Bichromate of Potassium nine ounces [avoirdupois]; Sulphuric Acid six fluid ounces and a half [Imp. meas.]; Solution of Soda a sufficiency; Water half a gallon [Imp. meas.]. Dilute the Sulphuric Acid with ten fluid ounces of the Water, and dissolve the Bichromate of Potassium in the remainder of the Water with the aid of heat. When both liquids are cold, mix them with the Amylic Alcohol in a retort or flask, with occasional brisk agitation, until the temperature of the mixture has fallen to about 32.2° C. (90° F.). Connect with a condenser, and distil until about half a gallon of liquid has passed over. Saturate the distilled liquid accurately with the Solution of Soda, remove any oily fluid which floats on the surface, evaporate till watery vapor ceases to escape, and then raise the heat cautiously so as to liquefy the salt. When the product has cooled and solidified, break it into pieces, and immediately put it into a stoppered bottle." *Br.* 1885.

The above process consists of two steps: first, the artificial formation of valeric acid, and, second, the saturation of this acid with sodium hydroxide. By distilling fusel oil with a mixture of sulphuric acid and potassium dichromate, valeric acid is formed, and passes over with water. The change is effected by the oxidizing agency of the chromic acid of the dichromate, for when the amyl alcohol of the fusel oil loses two atoms of hydrogen by oxidation, and gains one of oxygen, it is converted into valeric acid; thus,

(See *Potassii Dichromas*, and *Amyl Alcohol*, p. 1381.) The distillate, by exact saturation with the solution of sodium hydroxide, is converted into a solution of sodium valerate, which, by the application of heat until the water is driven off and the residual matter is partially liquefied, furnishes, on cooling, the concrete salt. The small portion of oil that floats on the surface of the solution is amyl valerate, $C_4H_9COOC_5H_{11}$.

Sodium valerate is a deliquescent, very soluble salt, in snow-white masses, having the disagreeable odor of valeric acid, and a taste at first styptic, but afterwards sweetish. When heated to 140.5° C. (285° F.), it fuses without loss of acid, and upon cooling concretes into a white solid. The salt, as formerly official, is in the form produced by fusion. Its formula is C_4H_9COONa . It is little used medicinally, having been originally introduced into the Dublin Pharmacopœia in 1850 for the sole purpose of forming, by double decomposition, iron, quinine, and zinc valerates. *Dose*, as a nervous stimulant, one to five grains (0.065–0.32 Gm.).

Soja. *Soja hispida*, Moench. (*Glycine hispida*, Maxim.) *Soy Bean.* *Soja* or *Sahuca Bean.* *Miso.* (Fam. Leguminosæ).—Meissel and Böcker (*A. J. P.*, 1885, 108) give the composition of soja bean

as follows: water, 10 per cent.; soluble casein, 30; albumen, 0.5; insoluble casein, 7; fat, 18; cholesterol, etc., 2; dextrin, 10; starch, 5; cellulose, 5; ash, 5; traces of sugar and an amido compound. Stingl and Morawski (*Monatsschrift für Chemie*, April, 1886) have determined the presence in this bean of a ferment said to be one of the most powerful known in its action upon starch, two-thirds of which it converts into sugar and one-third into dextrin. The amount of starch present in soja bean is so little that bread made from the meal may be used in diabetes. (*A. J. P.*, 1896, 309.)

Solanine.—This alkaloid, which is found in many species of the genus *Solanum*, is most conveniently obtained from the sprouts of the common potato, by Wackenroder's process, which may be found detailed in the 16th edition of *U. S. D.* Its formula is variously given by different authorities. According to Kletzensky, it is $C_{42}H_{56}NO_{14}$; according to R. Firbas, it is $C_{52}H_{92}NO_{18}$; and Hilger states that it is $C_{42}H_{87}NO_{15}$. Adrian asserts that it is a glucoside, and by heating with sulphuric or hydrochloric acid it breaks up into glucose and a second base, *solanidine*. This was confirmed by Zwenger and Kind, who give to solanidine the formula $C_{26}H_{41}NO_2$. Cazeneuve and Bretem (*J. P. C.*, 1888, 465) also agree that it is a glucoside and give it the formula $C_{28}H_{47}NO_{10} + 2H_2O$. Solanine is in the form of a white opaque powder, or of delicate acicular crystals, somewhat like those of quinine sulphate, though finer and shorter. It is odorless, of a bitter taste, fusible at from 112.7° to 115.5° C. (235°–240° F.), decomposing at a slightly higher temperature with an odor of caramel, a sublimate of solanidine forming. It is scarcely soluble in water, soluble in alcohol and ether, and capable of neutralizing the acids. It is distinguished by the deep brown or brownish-yellow color which iodine imparts to its solution, and by its reaction with sulphuric acid, which becomes first reddish-yellow, then purplish-violet, then brown, and, lastly, again colorless, with the deposition of a brown powder. This test is said not to be interfered with by the presence of morphine. (*A. J. P.*, 1873, 484.) The salts which solanine forms with acids are mostly amorphous in character. The oxalate, chromate, and phosphate form crystalline crusts. The acid sulphate is said to be very stable, and is not decomposed by water even on heating, in contradistinction to the neutral salt. It is amorphous and very bitter.

The physiological action of solanine has been studied by several investigators, with not altogether concordant results. Geneuill (*B. G. T.*, tome iii.) finds that it has a depressing influence upon the medulla, spinal cord, and both motor and sensory nerve trunks. In an elaborate investigation, Max Perles (*A. E. P. P.*, Leipzig, 1889, xxvi.) has determined that solanine acts as a powerful poison upon all forms of living protoplasm. When mixed with the blood outside of the body it causes rapid coagulation with alteration of the blood corpuscles. In the frog it produces a centric paralysis, with later paralysis of the heart. When injected intravenously it causes in mammals violent dyspnea, with cramp, arrest of respiration, and the presence of thrombi in the blood vessels. Toxic doses given by the mouth produce excitement, with tremors, fibrillary contractions, cramp followed by central paralysis, collapse, and death in deep coma, preceded by a fall of temperature which is so great as to be

almost characteristic. Vomiting and diarrhoea were frequently observed, and after death inflammation of the gastro-intestinal mucous membranes, and also a parenchymatous and even hemorrhagic nephritis. During life the urine was albuminous, containing casts, and not rarely was dark red from hemoglobin, or sometimes methæmoglobin. According to Capparoni, minute doses of solanine, while diminishing the rapidity of the heart's action, increase at the same time the arterial pressure.

In the researches of Max Perles, the action of *solanidine* was very similar to that of solanine, the chief difference between the two being that solanine is a violent local irritant, while *solanidine* seems free from local irritant properties. The two poisons are stated to belong physiologically to the sapotoxin group.

Solanine has been used by Geneuil, Capparoni, Vulpian, and others with asserted good results in *asthma*, to relieve the cough of *bronchitis*, to quiet the irritation of *cystitis* in the old, and for the relief of *gastralgia*, *pruritus*, *sciatica*, and other neuralgic or rheumatic pains. Capparoni (*B. G. T.*, May, 1888) affirms that it is an excellent analgesic, calming *ataxic* pains, and that it is even capable of controlling the tremors of lateral sclerosis.

Solanine has, however, been tried by various clinicians without results favorable to its use in practical medicine. (*Consult B. and F. Med.-Chir. Rev.*, July, 1854, Am. edition, p. 189; *A. G. M.*, March, 1859, p. 360; *B. G. T.*, July 15, 1887.) The dose of solanine, as given by different writers, varies. Frommüller has seen as much as 0.5 gramme (7.5 grains) taken without producing anything more serious than marked malaise, general weakness, giddiness, and sleep. Clarus gives the medium dose for adults as one-tenth to one-sixth grain (0.006–0.01 Gm.) of the acetate, and has seen six grains (0.4 Gm.) of the same salt produce general cephalic distress, with occipital pain, dyspnoea, increase of the frequency and loss of the force of the pulse, followed after some hours by sudden vomiting, diarrhoea, great weakness, and marked dyspnoea. Capparoni administered from three and three-fourths to four and one-half grains (0.25–0.30 Gm.) during the twenty-four hours in divided doses. It is probable that much of the solanine that has been used by investigators has been impure, and it would hardly be safe to begin with the pure alkaloid in the dose of more than one-fourth of a grain (0.016 Gm.), increasing the dose *pro re nata*. Cases of poisoning by potatoes in poor condition have been reported in Germany (*A. E. P.*, xxxvi.). The symptoms have been vomiting and diarrhoea with abdominal pain, headache, giddiness, and pronounced fever (102.2° F.); it is probable, however, that these manifestations were due to decomposition products rather than to solanine.

Solanum.—The genus *Solanum* contains a number of species which are possessed of active physiological properties, and some of which have been used to a considerable extent in medicine.

S. aculeatissimum, Jacq., known as *Apple of Sodom*, is indigenous to Brazil; the fruit yields traces of solanine.

S. bacciferum, of Jamaica, yields the so-called *Susumber berries*, which are habitually used as fruit by the natives, but Manners has recorded in the *Ed. M. J.*, 1867, fatal poisoning by these berries, death being preceded by dilated pupils and

collapse. It is probable, however, that the berries were not true *susumber berries* but were the product of some other species of *solanum*.

S. carolinense, L. *Horse Nettle*. *Sand Brier*. *Poisonous Potato*. *Apple of Sodom*.—A coarse perennial weed which grows in waste sandy ground in the United States as far west as Iowa and as far south as Florida, and yields an orange-yellow berry which is said to be the most active part of the plant. For study of microscopic structure, see *A. J. P.*, vol. lxi. It has been examined by G. A. Krauss (*A. J. P.*, 1890, 601, and 1891, 65 and 216) and Harry Kahn (*A. J. P.*, 1891, 126). Krauss found two active principles corresponding probably to *solanine*, $C_{42}H_{75}NO_{15}$, and *solanidine*, $C_{41}H_{71}NO_2$, together with a characteristic organic acid to which he gives the name *solanic acid*. J. U. Lloyd believes that the alkaloid in this plant is not identical with solanine, and proposes to call it *soline*. (*A. J. P.*, 1894, 61, and 1897, 76, 89, 108.) E. Q. Thornton (*T. G.*, xii. 1896) finds that in frogs this *solanum* produces stupor with tetanic spasms, not prevented by section of the cord. It is said to have long been used by the negroes of the South in the treatment of the so-called falling sickness, and in 1839 it was recommended by J. L. Napier as of value in epilepsy.

S. carolinense has been largely used in public and private practice for the relief of *epilepsy* by H. C. Wood, who has found that, although when given by itself its usefulness is very limited, as an adjuvant to the bromides it lessens the size of the doses necessary to keep the convulsions in check. Not less than a fluidrachm (3.75 Cc.) of the fluidextract should be given three times a day. No unpleasant effects have ever been produced by it.

S. Chenopodium.—In this plant, which is a native of Queensland, C. E. Sage has found the alkaloid *solanine*. According to E. B. Ormerod the plant is very useful in the treatment of *dysentery*. (*P. J.*, lxviii. 1902.)

S. Dulcamara, L. *Stipites Dulcamara*. *Tiges de Douce-amère* (de Morelle grimpante), *Douce amère*, Fr. *Bittersüss*, *Bittersüss-Stengel*, Alpranken, G. *Dulcamara*, It., Sp.—The young branches of this species were recognized in the *U. S. Pharmacopœia* of 1890 under the names of *Dulcamara* or *Bittersweet*. *S. Dulcamara* is a climbing shrub with a woody branching stem and purplish, cymose flowers, with lemon-yellow anthers. The bright scarlet berries remain after the falling of the leaves. The plant is common to Europe and North America, and in the United States grows from New England to Ohio. All portions of the plant are very active. Fatal results from the eating of the berries by a child have been recorded (*P. J.*, 1861). For medicinal purposes the plant should be gathered in the autumn after the fall of the leaf, and the extreme twigs should be selected. That grown in high and dry situations is said to be the best.

The dried twigs are of various lengths, cylindrical, about as thick as a goose quill, externally wrinkled, and of a grayish-ash color, consisting of a thin bark, an interior ligneous portion, and a central pith. They are inodorous, though the stalk in the recent state emits, when bruised, a peculiar, rather nauseous odor. Their taste, which is at first bitter and afterwards sweetish, has given origin to the name of the plant. "About 5 Mm., or less, thick, cylindrical, somewhat angular, longitudinally striate, more or less warty, usually hollow in the center, cut into

short sections. The thin bark is externally pale greenish, or light greenish-brown, marked with alternate leaf-scars, and internally green; the greenish or yellowish wood forms one or two concentric rings. Odor slight; taste bitter, afterwards sweet." *U. S.* 1890. Boiling water extracts all their virtues. These are supposed to depend, at least in part, upon the alkaloid *solanine*, which was originally discovered in 1821 by Desfosses of Besançon, in the berries of *Solanum nigrum*, L. Winckler (1841) first observed that the alkaloid of dulcamara stems can be obtained only in an amorphous state, and that it behaves to platinic and mercuric chlorides differently from the solanine of potatoes. Moitessier (1856) confirmed this observation, and obtained only amorphous salts of the solanine of bittersweet. Wittstein (1852) supposed another alkaloid, *dulcamarine*, to be present, but Geissler (1875) showed that this substance was a glucoside, and not an alkaloid, yielding on decomposition with dilute acids *dulcamaretin* and sugar. He assigned the formula $C_{25}H_{34}O_{10}$ to *dulcamarine*, and $C_{16}H_{28}O_6$ to *dulcamaretin*. (Flückiger, *Pharmacographia*, 2d ed. p. 451.) (For account of *solanine* see previous article.) Besides *solanine*, the stalks of *S. Dulcamara* contain, according to Pfaff, a peculiar principle to which he gave the name of *picroglycon*, indicative of the taste, at once bitter and sweet, which it is said to possess. This was obtained by Blitz, in the following manner: The aqueous extract was treated with alcohol, the tincture evaporated, the residue dissolved in water, the solution precipitated with lead subacetate, the excess of this salt decomposed by hydrogen sulphide, the liquor then evaporated to dryness, and the residue treated with acetic ether, which yielded the principle in small isolated crystals by spontaneous evaporation. Pfaff found also in *dulcamara*, gummy extractive, gluten, green wax, resin, benzoic acid, starch, lignin, and various salts of lime. Frederick Davis (*Y. B. P.*, 1902) found the two alkaloids, *solanine* and *solanidine*, the glucoside *solanine*, and the bitter principle *dulcamarin*, in fresh specimens of the plant.

Dulcamara possesses feeble narcotic properties, with the power of increasing the secretions, particularly those of the kidneys and skin. George B. Wood observed, when the system was under its influence, a dark purplish color of the face and hands, and at the same time considerable languor of the circulation. In overdoses it produces nausea, vomiting, faintness, vertigo, and convulsive muscular movements. A man took from three to four quarts of a decoction made from a peck of the stalks, and was attacked with pain in the joints, numbness of the limbs, dryness of the mouth, and palsy of the tongue, with consciousness unimpaired, the pulse quiet, but small and rather hard, and the skin cool; followed by recovery. (*London Med. Gaz.*, 1850.)

Anaphrodisiac properties have been attributed to *dulcamara*, and it has also been employed with alleged benefit in chronic *rheumatism*. But its chief use has been in the treatment of scaly cutaneous eruptions, such as *lepra*, *psoriasis*, and *pityriasis*. It has been usually administered in the form of a decoction, but the fluidextract, which was official in the *U. S. Pharmacopœia* of 1890, affords the best form of administration (see below.) *Dulcamara* may be given in doses of from 30 grains to a drachm (2-3.9 Gm.).

Extractum Dulcamaræ Fluidum. U. S. 1890. *Fluid Extract of Dulcamara*.—"Dulcamara, in No.

60 powder, one thousand grammes [or 35 ounces av., 120 grains]; Diluted Alcohol, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with four hundred cubic centimeters [or 13 fluidounces, 252 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until the *Dulcamara* is exhausted. Reserve the first eight hundred cubic centimeters [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluid Extract measure one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms]." *U. S.* 1890.

The foregoing formula differs from that of the *U. S. P.* 1870 in the absence of glycerin. This fluidextract of *dulcamara* is a rather thick, dark brown liquid. The dose is from thirty minims to a fluidrachm (1.8-3.75 Cc.), three or four times a day, which is gradually increased if necessary.

D. Freire has obtained from the fruit of *S. grandiflorum*, or wolf fruit, of Brazil, an energetic toxic alkaloid, *grandiflorine* (*C. R. A. S.*, cv.).

S. Jacquinii, Willd., is used in India as a diaphoretic and expectorant.

S. Lycopersicon, L. (*Lycopersicon Lycopersicon* (L.), Karst., *L. esculentum*, Mill.), formerly the *Love Apple*, now the *Tomato Plant*.—The tomato is believed by many practitioners to be an injurious article of diet to gouty persons on account of the great acidity of the juice, an acidity which T. D. McElhenie has demonstrated to be due at least in part to citric, malic, and oxalic acids (*A. J. P.*, 1872). *Solanine* is said not to be present in the juice but has been found by George W. Kennedy (*P. J.*, 1873) in the herbaceous part of the plant. It probably also exists in the seeds (*A. J. P.*, xxxiv.).

S. nigrum, L. *Black or Garden Nightshade*. *Duscle*. *Hound's Berry*. *Morelle*.—This is an annual plant, widely distributed in the United States from Texas to Nova Scotia. The leaves have been used in medicine in the treatment of *scrofulous dyscrasias*, and are said to produce diaphoresis when in overdose; also nausea, purging, and nervous disturbance. The poisonous properties commonly attributed to this plant are, however, to be doubted, since Dunal of Montpellier, states, as the result of numerous experiments, that the berries are not poisonous to man or the inferior animals; and the leaves are said to be consumed in large quantities in the Isles of France and Bourbon as it is in the Hawaiian Islands by the natives as food, having been previously boiled in water. In the latter case the active principle of the plant may have been extracted by decoction. Introduced by importers under the name of *jurubeba*, this plant was examined by Kobert and found to contain an active principle, and to be inert. According to Peckoldt, however (*Ph. Rund.*, 1889), true *jurubeba* is *Solanum insidiosum*, Mart., from which the results would have been more favorable. It is used in Brazil in *gonorrhœa* and *syphilis*

S. Pseudocapsicum, L., or *Jerusalem Cherry*, yields a fruit whose resemblance to the common cherry is said to have led to its being eaten by children with fatal results.

S. rostratum, Dunal. *Sand Bur. Beaked Nightshade. Bull Nettle*.—This plant, which grows on the prairies from Nebraska to Mexico, and is noteworthy as having been the original food of the Colorado beetle or potato bug, has yielded to W. S. Amos an alkaloid (*Notes on N. R.*, iv.). Narcotic properties have been attributed to the leaves, stalks and unripe berries of *S. tuberosum*, L., or common white potato, and the extract has been used in various diseases. Worsham of Philadelphia, found the extract, in the quantity of nearly one hundred grains, to cause no sensible effect. (*Phila. Journ. of the Med. and Phys. Sciences*, vi. 22.) It is probable that the properties of the plant vary with the stage of growth, or with the place and circumstances of culture, as is indicated by the researches of C. Haaf, who found solanine in old potatoes which had begun to germinate, in the proportion of 0.16 in 500 parts, and in very young potatoes, deprived of their coating, precisely the same quantity. Fully ripe potatoes, which had not begun to sprout, gave a negative result. (*N. R. Pharm.*, 1864, p. 559.) Solanine has also been found in the germs of potatoes by Julius Otto, and a case is recorded of death in a girl of fourteen, from eating the unripe fruit of the potato (*B. M. J.*, Sept. 3, 1859). The prominent symptoms were partial stupor, speechlessness, jactitation, hurried breathing, lividness of the skin, cold sweats, very frequent and feeble pulse, and a constant spitting through the closed teeth of viscid frothy phlegm.

Solidago. *Golden-rod. Verge d'Or*, Fr. *Gold-ruthe*, G.—There are very numerous species of this composite genus in the United States. Of these *S. odora*, Ait., was formerly official. *S. Virgaurea*, L., which is common to the United States and Europe, was formerly directed by the Dublin College. It is aromatic, astringent, in hot infusion diaphoretic, and is asserted to be diuretic. (*Rev. Gén. de Clin. et de Thérap.*, 1889.) For a study of the flowers of *S. bicolor*, L., by Adam Conrath, see *A. J. P.*, 1873, 253. For an analysis of *S. rugosa*, Mill., see *A. J. P.*, 1893, 122.

Solphinol.—A white, odorless, crystalline powder, consisting chiefly of boric acid, borax, and alkaline sulphites. It is soluble in ten parts of water and twenty parts of glycerin. It is used as a surgical antiseptic.

Soluble Mercury of Hahnemann. NH_2 (Hg_2) NO_3 .—This is prepared by adding, drop by drop, a diluted solution of ammonia to an equally diluted solution of mercurous nitrate, until the precipitate begins to be paler than at first. It is a black powder. When it has a gray color, the fact shows that too much ammonia has been employed in its precipitation. In this case NH_2 (Hg_2) NO_3 yields NH_2 (Hg) NO_3 + Hg . This preparation was included in the old French Codex. It has been used in syphilitic diseases.

Solution of Chlorinated Potassa. *Liquor Potassæ Chlorinatæ. Chlorure de Potasse*, Fr. *Chlorkalilösung*, G. *Javelle's Water. Eau de Javelle*.—This is prepared from potassium carbonate precisely as the solution of chlorinated soda is from sodium carbonate, and has an analogous composition. (See *Liquor Sodæ Chlorinatæ*, p. 736.) It is employed for taking out fruit stains, etc., from linen.

Solution of Dialyzed Iron. *Liquor Ferri Dialysatus. Liquor Ferri Oxychlorati*, P. G.—*Dialyzed Solution of Iron* was formerly recognized by the Br. Ph., but was dismissed at the last revision. It is made by treating a solution of ferric chloride with ammonia, whereby ferric hydroxide is precipitated, which by agitation is dissolved, placing the thick liquid in a dialyzer, and suspending this in water, which is to be constantly renewed so long as any traces of hydrochloric acid are found in it. The following process has been used in the United States: To one hundred parts of solution of ferric chloride, sp. gr. 1.26, thirty-five parts of ammonia water, sp. gr. 0.923, may be gradually added. The precipitate which almost immediately forms is redissolved, and the solution introduced into the dialyzer, which is then suspended upon the water, contained in a suitable vessel. When this ceases to produce a precipitate with silver nitrate, or to show an acid reaction, it is assayed by evaporating 10 Cc. to dryness on a water bath, to ascertain the amount of ferric oxychloride in solution; then the final solution is diluted so that it shall contain 10 per cent. of dry oxychloride.

Dialyzed iron is a solution of ferric oxychloride in water. Although the amount of chlorine present is very small, it is not correct to speak of it as a solution of ferric oxide. Its composition may vary from $\text{Fe}_2\text{Cl}_6.12\text{Fe}_2\text{O}_3$ to $\text{Fe}_2\text{Cl}_6.95\text{Fe}_2\text{O}_3$ (Graham), and solutions which contain a large quantity of oxide in proportion to chloride are less stable and more prone to gelatinize. Solutions containing a large proportion of chloride may be evaporated to dryness, if care be used, without the residue becoming insoluble. The solution is of a transparent reddish-brown color, free from the usual astringent, styptic taste of iron preparations. It mixes in all proportions with distilled water, alcohol, syrup, and glycerin, but water containing any saline impurity is apt to cause precipitation. When gelatinization occurs, agitation with a small quantity of solution of ferric chloride will usually restore it to fluidity, care being observed not to add an excess. Contact with the alkalis should be avoided, even in minute quantity; indeed, it is best administered without addition of any kind, or simply diluted with distilled water.

The British Pharmacopœia formerly directed that its specific gravity should be 1.047, and "100 grains should afford a precipitate with a solution of ammonia which, washed, dried and ignited, weighs five grains." E. B. Shuttleworth (*Can. Pharm. Journ.*, Dec. 1877) recommends a solution which has the sp. gr. 1.040 and yielding 5 per cent. of residue when well dried on a water bath, as the best for medicinal use. The specific gravity test can be relied upon, if the solution does not give a precipitate with silver nitrate or become of a blackish-blue color upon treatment with tannin, showing the absence of ferric chloride. (See also *N. R.*, 1879, 46, for a new process by F. Schneider, from *S. W. P.*, 1878, 409.) There is good reason for believing that much of the so-called dialyzed iron found in commerce is made by adding freshly precipitated ferric hydroxide to solution of ferric chloride until it ceases to be dissolved, and then filtering the solution. (Scheffer, *A. J. P.*, March, 1878.) *Ferrum catalyticum*, or *catalytic iron*, used on the Continent, is probably made in this way.

Solution of dialyzed iron has been very highly praised as a ferruginous tonic free from astrin-

gency, which can be given in enormous doses without producing headache or gastro-intestinal irritation. It is evident, however, that a preparation which will not pass through animal membrane cannot be absorbed; in fact, dialyzed iron is precipitated in the stomach and intestines as a ferric oxide, which is very slowly absorbed. Dialyzed iron is, therefore, not an eligible preparation. It is capable of acting as an antidote to arsenic by virtue of the readiness with which it yields hydrated ferric oxide, but it is safer to depend upon the official antidote, ferric hydroxide with magnesium oxide (see p. 506). *Dose*, from one-half to one fluidrachm (1.3-3.75 Cc.).

Solution of Magnesium Bisulphite. *Liquor Magnesii Bisulphitis*.—George Archibald, having found that magnesium bisulphite is capable of arresting the butyric acid fermentation, proposed a solution of it as a remedy in *heartburn*. He prepared it by treating the magnesium carbonate with sulphurous acid, adding to an ounce of water sixteen grains of the sulphite thus formed, and passing sulphurous acid gas through the mixture until a clear solution is obtained. (*P. J.*, 3d series, ii. 502.)

Solutol.—An alkaline solution of sodium cresol in an excess of cresol. It is a transparent brownish liquid, miscible with water, and is used for disinfecting purposes.

Solveol.—A solution of sodium-cresylate in cresol. It is less caustic than solutol, is nearly odorless, of a neutral reaction, and miscible with water. It is used as a surgical antiseptic, for dressings, and in spray apparatus.

Somatose.—This is an artificially digested meat albumin containing 51.6 per cent. of deuterio and 13.4 per cent. of hetero-albuminose, 5 per cent. of peptone, 1 per cent. of moisture, and 5 per cent. of nutrient salts. A yellowish, odorless, and almost tasteless powder.

Iron Somatose is a similar preparation containing 2 per cent. of iron in combination.

Milk Somatose is a soluble nutrient prepared by the same digestive process from casein, containing 5 per cent. of tannin. It is a light yellowish powder, readily soluble in water.

Somnal. $C_7H_{12}Cl_3O_3N$.—This is said to be a solution of hydrated chloral and urethane in alcohol. Teheremshansky, in a physiological study, has found that it acts upon the nerve centres and upon the circulation almost exactly as does chloral, it being, however, a little less depressing to the heart. Myers (*N. Y. Med. Rec.*, 1892) has reached similar conclusions.

Somnal, therefore, appears to be physiologically equivalent to a mixture of hydrated chloral and urethane, and it does not seem to be clear that it possesses any advantage over the older remedies. It may be given in *doses* of from one-half to one fluidrachm (1.8-3.75 Cc.), although much larger quantities have been occasionally prescribed by some clinicians.

Somnoform.—A proprietary anæsthetic said to contain ethyl chloride 60 per cent., methyl chloride 35 per cent., ethyl bromide 5 per cent. (For a study of its physiological action, see *B. M. J.*, 1903, 1.)

Somnos. $(CCl_3.CH<\overset{OH}{O})_3, C_3H_5$.—It is formed by the interaction of anhydrous chloral and glycerol, which react like chloral and alcohol in the formation of chloral alcoholate. The commercial preparation is an alcoholic solution of the compound.

Somnos is used as a hypnotic, the claim made for it that it is free from the depressant effects of chloral does not appear to be sustained.

Dose, of the commercial solution, one fluidrachm (3.75 Cc.).

Sonchus. *Sonchus oleraceus*, L. *Sow Thistle*. (*Fam. Compositæ*.)—The brownish gum left after the evaporation of the juice of this plant is said to be a powerful hydragogue cathartic, in *doses* of from two to four grains (0.13-0.26 Gm.). Combined with aromatics or belladonna, it may be used instead of elaterium in *dropsy*. (*Med. Bull.*, July, 1888.)

Soot. *Fuligo Ligni*.—This well-known substance has a peculiar odor, and a bitter, empyreumatic, and disagreeable taste. Its composition varies according to the source and conditions of its formation. When obtained by the combustion of resinous materials it may contain oily distillation products soluble in ether; when obtained by the combustion of wood it may contain pyroigneous (acetic) acid and products peculiar to wood tar, such as creosote, guaiacol, and phenols. Of course mineral substances from the ash of the wood may also be present.

Soot was formerly official with the Edinburgh College, and the Scotch physicians prescribed it as a tonic and antispasmodic. It has also been employed as an external remedy in skin diseases. (See *Révue Méd.*, June, 1834; *B. G. T.*, Mars, 1834; also 14th ed. *U. S. D.*) A few shovelfuls of it, thrown into privies or drains, effectually destroy their foul exhalations.

Sophora. *S. secundiflora* (Cav.), DC. (*S. speciosa*, Benth.) *Coral Bean*.—From the poisonous seeds of this leguminous Texan tree H. C. Wood obtained a volatile liquid alkaloid (*sophorine*) whose chloride is crystalline (see *A. J. P.*, 1878), and which, according to P. C. Plugge, is identical with cytisine. This same alkaloid probably exists in many species of the genus, as Parsons found a liquid alkaloid in *S. sericea*, Nutt., *crazy-weed*, which grows in Colorado and Mexico (*Rep. Commissioner of Agricult.*, 1879, and *N. R.*, 1881, 67; see also reports of an investigation by Kalteyer and Neil, *A. J. P.*, 1866, 465), and Greshoff (*P. J.*, xxii.) one in *S. tomentosa*, L. Plugge, however (*A. Pharm.*, 1895), affirms that *matrine*, the alkaloid discovered by Nagai in *S. angustifolia*, is distinct from cytisine.

Sorbus. *Sorbus Aucuparia*, L. (*Pyrus Aucuparia*, Gaertn.) *Mountain Ash*. *Sorbes*, Fr. *Eberesche*, Vogelbeere, G. (*Fam. Rosaceæ*.)—A small European tree, whose fruit contains a peculiar kind of sugar called *sorbinose*, $C_6H_{12}O_6$, isomeric with levulose. It reduces Fehling's solution, but is not fermentable with yeast. Hofmann has also discovered two new acids, which he designates as *sorbic* and *parasorbic acids*, $C_6H_8O_2$. Sorbic acid forms colorless needle-like crystals fusing at 134.5° C. (274° F.), while parasorbic acid is a lactone-like body, which, on heating with concentrated acids or solid alkali, changes into sorbic acid. M. J. Boussingault has found in it a crystalline saccharine principle, *sorbitol*, isomeric with mannitol, melting, when anhydrous, at from 110° to 111° C. (230°-231.8° F.), when hydrated, at 102° C. (215.6° F.). Its formula is $C_6H_{14}O_6$. It does not undergo the vinous fermentation. (*P. J.*, 1872, 28.) The fruit has been used in *scurvy*, and, in infusion, as a remedy in *hemorrhoids* and *strangury*. All parts of the tree are astringent, and may be employed in tanning and dyeing black. *S. americana*, Marsh. (*Pyrus americana*, DC.),

or *American Mountain Ash*, probably has similar virtues to the European species. Edwin Johanson found the fruit to yield from 4.92 to 6.6 per cent. of malic acid. (*Ph. Z. R.*, i. 1882.)

Sorghum.—*Sorghum*, or *Chinese Sugar cane*, is yielded, according to Hoekel, by a number of varieties of *Andropogon arundinaceus*, Scop. (*Sorghum vulgare*, Pers., *A. Sorghum*, Brot.). Some of the varieties indigenous in India, China, and other parts of the East have within recent years been introduced into Europe and the United States. It has come largely into cultivation in the United States, owing in great part to the efforts of the Department of Agriculture, whose numerous publications upon the subject may be consulted by any one desirous of information.

Sozal. ($\text{C}_6\text{H}_4(\text{OH})(\text{SO}_3)_2\text{Al}$. *Aluminum Paraphenolsulphonate*.—This is obtained by dissolving aluminum hydrate in paraphenolsulphonic acid, or by double decomposition of aluminum sulphate and barium paraphenolsulphonate. It occurs in crystalline grains having a weak phenol odor, but strongly astringent taste; easily soluble in water, glycerin, and alcohol, forming permanent solutions. It has been used as an antiseptic in place of iodoform. (*Ph. Ztg.*, 1892.)

Soziodolic Acid. *Soziodol*. *Diiodoparaphenolsulphonic Acid*. $\text{C}_6\text{H}_2\text{I}_2(\text{SO}_3\text{H})\text{OH}$.—This is a white glistening powder, odorless, of slightly acid taste, slightly soluble in cold water, more easily in hot water. It is decomposed on heating to 200°C . (392°F .), giving off violet vapors. It contains about 53 per cent. of iodine. It can be recognized by heating, or by adding sulphuric acid to it in hot solution, when iodine separates. Ferric chloride imparts a dark violet color to the aqueous solution; silver nitrate throws down a white precipitate of silver soziodol completely soluble in diluted nitric or sulphuric acid. For an outline of the process of manufacture, see *Squibb's Ephem.*, Feb. 1893. Soziodol is used as a local remedy, resembling somewhat iodoform in its range of usefulness. According to Langaard, 2 per cent. is sufficient to kill bacteria of pus; for wounds, a 10 per cent. mixture with powdered tale is advocated. Lassar praises it in *eczema*, *herpes tonsurans*, *impetigo*, etc.; it has also been much used in *otitis* and *rhinitis*. Langaard has found that fifteen grain doses have no appreciable effect upon rabbits, and Bufalini gave twenty-two grains a day in *phthisis* without unpleasant effect. The following salts have been used.

Sodium soziodol, readily soluble; used in all cases where aqueous solutions are employed. *Potassium soziodol*, sparingly soluble; a desiccant indicated in *eczema*. It is usually employed with tale in the proportion of 1:5 or 1:6. *Zinc soziodol*, a local irritant in solutions of from 1:20 to 1:50; a caustic in a solution of 1:5. *Mercury soziodol*, a caustic, even in a solution of 1:10. Miller affirms that its solution of $2\frac{1}{2}$ in 100 kills the acarus of *scabies* in twenty-four minutes.

Sozolic Acid. *Acidum Sozolicum*. *Orthophenolsulphonic Acid*. $\text{C}_6\text{H}_4(\text{SO}_3\text{H})\text{OH}$.—Ortho and paraphenolsulphonic acids are both formed when phenol is dissolved in concentrated sulphuric acid; at medium temperatures the former is far more abundant, but it readily passes into the para compound on the application of heat. Sozolic acid has a very faint odor of phenol. It is readily soluble in water, alcohol, and glycerin, and is used so diluted as to contain from 3 to 10 per cent. of the active principle. The orthophenolsulphonic acid in $33\frac{1}{3}$ per cent. solution has

received the trade name of *aseptol*. The ortho acid changes on heating into the isomeric paraphenolsulphonic acid, and this change takes place even in the aqueous solution of the former, a fact which should be remembered in the preparation of aseptol solutions.

E. Riegler (*W. M. Bl.*, xviii. 1895) proposes aseptol as a test for albumin in urine. One part in 20,000 causes coagulation; the precipitate with albumin does not disappear with heat. The solutions of albuminose and peptones are also precipitated, but the precipitates of these disappear with heat. The solution of aseptol undergoes decomposition when exposed to light.

Schiff and Beilstein asserted that phenolsulphonic acid acts like tannic and gallic acids, precipitating albumen and alkaloids, and being capable of replacing gallic acid in the making of leather and in pharmacy. There is, however, no sufficient reason for believing that the substance can be used in medicine in the place of the vegetable acids named. It has also been asserted that phenolsulphonic acid is a more powerful antiseptic than phenol, having the great advantage of being nearly odorless, non-irritating, non-poisonous, and miscible with water in all proportions, therefore to be especially valuable in abdominal and ophthalmological surgery. That it is free from poisonous properties is not probable, and in a careful series of comparative experiments, F. A. Tucker (*Notes on New Remedies*, 1892) found that it had not more than one-third the antiseptic power of phenol.

Spartium. *Spartium junceum*, L. *Spanish Broom*. (Fam. Leguminosæ).—A small shrub, indigenous in the south of Europe, and cultivated in our gardens as an ornamental plant. The flowers are large, yellow, and of an agreeable odor. Spanish broom in its medicinal properties closely resembles *Scoparius*, but appears to be from five to six times more active, 6 Gm. of the dried plant, given in infusion, having produced very violent poisoning; serious results have been produced by the substitution of the Spanish for the true broom. The dried flowers are readily differentiated, those of the true broom having a small, bell-shaped calyx with two unequal lobes, the upper of which is bidentate, the lower minutely tridentate, and the style always rolled, while in *Spartium junceum* the calyx is deeply cleft to the base on one side only, and the style is deeply rolled.

The symptoms produced by overdoses are vomiting and purging, with renal irritation. The seeds have been used to a considerable extent in *dropsy* in doses of from ten to fifteen grains (0.65–1.0 Gm.) three times a day in the form of tincture.

Sphacelotoxin. *Spasmotin*. *Spasmotoxin*. $\text{C}_{20}\text{H}_{31}\text{O}_9$.—A crystalline yellow powder isolated by Jacoby from ergot. (*Amer. Therap.*, 1894, 295.) It is insoluble in water, in diluted acids, and in petroleum benzin; soluble in ether, alcohol, and benzene. It forms salts with alkalis, the sodium salt being recommended for hypodermic injections. It is asserted that sphacelotoxin is the active constituent of ergot. The dose is from one-thirtieth to one-twelfth of a grain (0.002–0.005 Gm.), but doses up to one grain (0.065 Gm.) have been given without danger.

Sphæranthus. *Sphæranthus indicus*, L. (Fam. Compositæ).—An Indian plant, which is used as a general tonic, deobstruent, alterative, and aphrodisiac, under the names of *Mundi*, *Gorakhmundi*, *Murmuri*, and *Kottakkarandai*. Dymock has found it in a deep cherry-colored essential oil.

Spider Poisons.—The popular belief that certain spiders have the power of poisoning small animals, and even man, has received confirmation, and an active principle, *arachnolysin*, has been separated by Sachs and found to have a powerful hæmolytic action upon the blood of rabbits and cats, but not to affect dogs and guinea pigs (see Kobert, *Giftspinnen*, 1901; *S. Jb.*, Bd. 274, 178).

Spilanthes. *Spilanthes Acmella*, Murr. (*S. oleracea*, L.) *Para Cress.* *Cresson de Para*, Fr. *Parakresse*, G. (Fam. Compositæ).—A plant of India, used as a masticatory for toothache; when chewed it produces a copious salivation. (*A. J. P.*, xliv. 323.)

Spiræa.—Many if not all of the species of this genus contain a colorless volatile oil, very similar to the oil of gaultheria, but composed mainly of salicylic aldehyde, with only smaller amounts of methyl salicylate. The species which have been submitted to actual analysis are the *Spiræa Ulmaria*, L. (*Filipendula Ulmaria*, Maxim., *Ulmaria palustris*, Moench.),—*Queen of the Meadow*, or *Meadow-sweet*,—a European plant which has been introduced into this country; also the European species *S. lobata*, Jacq., and the species *S. Filipendula*, L. (*Filipendula vulgaris*, Moench.), which grows in Southern Europe and Northern Africa. A yellow, crystalline powder of a bitter taste, insoluble in water, slightly so in alcohol, readily soluble in ether, and having an acid reaction. *Spiræic acid* (now recognized as salicylic acid) (*J. Pr. Chem.*, xix.) was separated from the flowers of *S. Ulmaria* by Löwig and Weidmann, and has been found by Rochebrune in the flowers of *S. Filipendula*, L.

The roots of probably most of the species contain tannic acid, gallic acid, and when fresh some of the volatile oils. (*A. J. P.*, 1887.) The root of *Spiræa tomentosa*, L. (*Hardhack*, *Steeplebush*, or *Whitecap*), was formerly recognized in the U. S. Pharmacopœia. It is an indigenous shrub, two or three feet high, with numerous simple, erect, round, downy, and purplish stems, furnished with alternate leaves, closely set upon very short footstalks. The leaves are ovate-lanceolate, unequally serrate, somewhat pointed at both ends, dark green on their upper surface, whitish and tomentose beneath. The flowers are disposed in terminal, compound, crowded spikes or racemes.

The flowers of the *Spiræa* possess to a very feeble extent the medicinal virtues of salicylic acid, and have been used as diuretic and tonic in the form of decoction. The roots are astringent, and have been used in the treatment of *diarrhœa* in doses of from five to twenty grains (0.32–1.3 Gm.) of the aqueous extract repeated *pro re nata*.

Splenic Extract.—Led by the spontaneous recovery of a severe case of exophthalmic goitre during an attack of abscess of the spleen, and the well-known relations between diseases of the spleen and myxœdema, H. C. Wood tried the splenic extract in various cases of *exophthalmic goitre* with sufficient results to make further clinical investigation incumbent upon the profession. The experiments of Oliver and Schäfer show that the intravenous injection of the splenic extract produces in the dog a primary fall and a secondary rise of the arterial pressure; beyond this we have no definite knowledge of the physiological action of the extract. It has been used by A. C. Clark with apparent beneficial results in a number of cases of *insanity* connected with nervous exhaustion. He states that it increases the activity of the skin, usually increases the appetite, and has no effect upon the

bowels, the urine, or the blood. In the practice of H. C. Wood a disadvantage has been the tendency of the extract to produce nausea, or, if used hypodermically in the form of the glycerin extract, to cause abscesses. In teaspoonful doses the glycerin extract (40 per cent.) has in some cases provoked violent gastric distress. *Dose*, of the glycerin extract, from ten to twenty minims (0.6–1.3 Cc.) three times a day; *dose*, of the solid extract, from three to five grains (0.2–0.32 Gm.), in capsules.

Sponge. *Spongia officinalis*. *Eponge*, Fr. *Schwamm*. *Badeschwamm*, G.—The sponge is “a flexible, fixed, torpid, polymorphous animal, composed either of reticulate fibres or masses of small spires interwoven together, and clothed with a gelatinous flesh, full of small mouths on its surface, by which it absorbs and ejects water.” Various genera are described, but the sponges used in commerce are said all to belong to the genus *Spongia*. Sponges inhabit the bottom of the sea, where they are fixed to rocks or other solid bodies, and are most abundant within the tropics. They are collected chiefly in the Mediterranean and Red Seas, and in those of the East and West Indies. When collected they are enveloped in a gelatinous coating, which forms part of the animal. For details of fishery and preparation, see *P. J.*, xx. Large quantities of the coarser kinds are imported from the Bahamas, but the finest and most esteemed are brought from the Mediterranean, especially from the coast of Syria. Recently the cultivation of sponges has been undertaken on an extensive scale. Small fragments are cut under water from the live sponge, and fixed upon a sandy bottom by means of skewers. In three years they will have grown sufficiently to be marketable.

Sponge, as found in commerce, is in yellowish-brown masses of various shapes and sizes, light, porous, elastic, and composed of fine, flexible, tenacious fibres, interwoven in the form of cells and meshes. It usually contains numerous minute fragments of coral or stone, or small shells, from which it must be freed before it can be used for ordinary purposes. Sponge is prepared by macerating it for several days in cold water, beating it in order to break up the concretions which it contains, and dissolving what cannot thus be separated of the calcareous matter by hydrochloric acid diluted with thirty parts of water. By this process it is rendered perfectly soft, and fit for surgical use. It may be bleached by steeping it in water impregnated with sulphurous acid, or by exposure in a moist state to the action of chlorine. It is stated that sponges which have been soaked in pus and infectious matters will recover their primitive condition by soaking in a 4 per cent. solution of potassium permanganate, then in a 25 per cent. solution of official sulphurous acid, and finally thorough washing in an abundance of water. (*A. J. P.*, xlv. 355.) When intended for surgical purposes, the softest, finest, and most elastic sponges should be selected; for forming *burnt sponge* the coarser will answer equally well. According to Hatchett, the chemical constituents of sponge are gelatin, coagulated albumin, common salt, and calcium carbonate. Magnesia, silica, iron, sulphur, and phosphorus have been detected in it, as also iodine and bromine, combined with sodium and potassium. From the experiments of Croockewit, it would appear that sponge is closely analogous to, if not identical with, the *fibroin* and *sericin*.

of silk, differing from it only in containing iodine, sulphur, and phosphorus. (*Ann. Ch. Ph.*, xlviii. 43.) Schlossberger, however, has shown that it is distinct, in its very slight solubility in ammoniacal solution of copper hydroxide and in its yielding leucine and glycecol when treated with diluted sulphuric acid, while sericin yields under similar treatment tyrosine and serin. He names the principle *spongina*.

Sponges are used for mechanical purposes only. *Sponge tent* is employed for dilating sinuses. This is prepared by dipping sponge into melted wax, compressing it between two flat surfaces till the wax hardens, and then cutting it into pieces of a proper form and size. By the heat of the body the wax becomes soft, and the sponge, expanding by the imbibition of moisture, gradually dilates the wound or sinus in which it may be placed. When a conical sponge tent of uniform calibre is required, as for dilating the uterine cavity, a better plan is to cut the sponge into a conical shape while fresh and compress when moist, by winding it carefully with a fine tightly drawn cord, removing the cord when perfectly dry, and dipping the tent into melted wax, so as to get a thick coating. For other modes of preparing sponge tent, as well as of saturating the sponge at the same time with substances calculated to make a remedial impression—as phenol, alum, lead acetate, etc., see *A. J. P.*, 1868, 410; 1869, 446.

Spongia Usta, *Burnt Sponge*, was formerly official (*Spongia Usta*, U. S. 1850), but is no longer used in medicine. For method of preparation, analysis, and therapeutic properties, see 16th edition, U. S. D.

Statice. *Statice caroliniana*, Walt. (*S. Limonium* (L.), Gray. *Limonium carolinianum* (Walt.), Britt.) *Marsh Rosemary*. *Ink Root*. *Sea Lavender*. *Romarin des Marais*, *Lavande triste*, Fr. *Strandnelke*, G. (Fam. *Plumbaginaceae*).—It is an indigenous maritime plant with a perennial root, sending up annually tufts of leaves, which are obovate or cuneiform, entire, obtuse, mucronate, smooth, and on long footstalks.

Marsh rosemary grows in the salt marshes along the sea coast from New England to Florida, and flowers in August and September. The root, which was formerly in the Secondary List of the U. S. Pharmacopœia, is large, spindle-shaped, or branched, fleshy, compact, rough, and of a purplish brown color. It is bitter and extremely astringent, but odorless. It contains tannic acid (12.4 per cent.), volatile oil, resin, and other substances (*A. J. P.*, xiv. 116). *Statice* is powerfully astringent, and in some parts of the United States, particularly in New England, is much employed, especially as a local application, in decoction, to aphthous and ulcerative affections of the mouth and fauces.

In Brazil and Buenos Ayres the roots of *S. brasiliensis*, Boiss., are employed under the name of *Buayoura* or *Guayoura*. (*P. J.*, 1878, ix. 466.) For a description of the physical and chemical characteristics of the root, see *P. J.*, vol. xv. 86. In Russia and Spain the very large roots of *S. latifolia*, Sm., are used for tanning, and in Morocco the roots of *S. mucronata*, L., are stated to be employed, under the name of *safrika*, as a nerveine.

Sterisol.—An antiseptic varnish made by dissolving purified gum lac 270 parts, benzoin 10 parts, balsam of Tolu 10 parts, phenol in crystals 100 parts, oil of cinnamon 6 parts, saccharin 6 parts, in sufficient alcohol to make 1000 parts. It

permits of asepsis of mucous surfaces, and is adapted for use where it is impossible to apply bandages.

Sterisol. *Steriosol*.—According to Aufrecht, this liquid contains formaldehyde, sodium chloride, potassium phosphate, sugar of milk, and water. It is used as an antiseptic.

Stipa.—According to Gillespie (*B. M. J.*, Oct. 1898), a number of species of this genus of grasses are actively poisonous, and have caused death in horses and other domestic animals. Of such character especially are *Stipa viridula*, Trin., *Stipa inebrians*, Hance, and *Stipa sibirica*, Lam., of the Russian steppes. A few experiments made with *Stipa viridula*, Trin., indicated that it acts powerfully upon the brain and spinal cord.

Stipa Vasevi, Scribner.—According to Vernon Bailey this grass, which grows on the mountains of California, is a very active narcotic, producing in animals, which graze upon it, sleep lasting for a week or longer.

Stovaine. *Amylene AB. Hydrochloride*. (*Hydrochloride of benzoyl ethylmethyl-aminopropanol*).—This substance, belonging to the group of amino-alcohols, was first brought before the French Academy of Medicine, March 24, 1904, by Billon, whose results have been confirmed by Lapersonne (*Recueil d'Ophthalmologie*, May, 1904). It crystallizes in small, brilliant scales, melting at 175° C. (347° F.), and is very soluble in water. It shows most of the reactions of cocaine, which is also a benzoyl derivative. It is affirmed to have very much less toxicity than cocaine. The solution when placed in the eye causes a rapid anæsthesia, with abolition of the palpebral reflexes, mild injection of the conjunctiva, and slight myosis. These symptoms usually pass off in from three to ten minutes, but when the applications are repeated two or three times at an interval of one minute profound anæsthesia, lasting from twenty to twenty-five minutes, is produced.

According to Lapersonne, stovaine as a local anæsthetic is inferior to cocaine for application to the conjunctiva, but contrarily is superior to cocaine for subcutaneous and subconjunctival use; and frequently, especially in ocular instillation, advantage is obtained by the use of a mixture of two parts of stovaine to one part of cocaine. The solutions used by Lapersonne were for instillation, 4 per cent.; for subconjunctival injection, 1 per cent.

Strontium Lactate. *Strontii Lactas*, U. S. 1890. $\text{Sr}(\text{C}_2\text{H}_5\text{O}_2)_2 \cdot 3\text{H}_2\text{O} = 317.32$.—This salt may be prepared by the process of Thumann, who takes a certain quantity of finely powdered strontium nitrate which is thoroughly washed on a funnel, closed with absorbent cotton, with strong alcohol; after drying, 44.84 Gm. of the strontium nitrate are dissolved in 1 liter of water and 10 Gm. of diluted sulphuric acid added, when all the barium present will be precipitated, together with a small quantity of strontium. The filtrate is treated with an excess of pure sodium carbonate (about 60 Gm. dissolved in 1 liter of water); the precipitated strontium carbonate is washed on a filter to free it from sodium carbonate and sodium nitrate. To the strontium carbonate, contained in a tared beaker, are added 36 Gm. of absolute lactic acid diluted with 200 Cc. of water, and the mixture heated until solution is effected; then sufficient water is added to make the solution weigh 551 Gm., which will then represent 10 per cent. of pure anhydrous strontium lactate. If the salt be desired, the solution may be evaporated, and

the residue granulated. This was officially described as "a white, granular powder, or crystalline nodules, odorless, and having a slightly bitter, saline taste; permanent in the air. Soluble in about 4 parts of water at 15° C. (59° F.), and in less than 0.5 part of boiling water. The solution saturated at a boiling heat remains liquid for many hours, even after being cooled to 0° C. (32° F.). Soluble in alcohol. When heated to 110° C. (230° F.), the salt loses its water (16.9 per cent.). At a higher temperature it first fuses, then is decomposed, giving off inflammable vapors, and leaves a residue of strontium carbonate and carbon, which, on the addition of hydrochloric acid, effervesces and communicates an intense, red color to a non-luminous flame. The aqueous solution (1 in 20) is slightly acid to litmus paper. With calcium sulphate test-solution the solution slowly forms a white precipitate of strontium sulphate, insoluble in diluted acids. The same reaction occurs more quickly with diluted sulphuric acid, potassium sulphate test-solution, or other soluble sulphates. With potassium chromate test-solution it forms a yellow precipitate of strontium chromate, soluble in acetic acid. With ammonium carbonate test-solution, or sodium carbonate test-solution, it forms a white precipitate of strontium carbonate, soluble, with effervescence, in acetic acid. If to 5 Cc. of the solution (1 in 20) 1 Cc. of sulphuric acid be added, and then 1 Cc. of potassium permanganate decinormal volumetric solution, the red color will rapidly disappear, while the mixture will effervesce and give off the odor of aldehyde. If 1 Gm. of the salt be dissolved in 19 Cc. of water, it should form a perfectly clear, colorless solution, leaving no insoluble residue (absence of carbonate, oxalate, etc.). The aqueous solution should not be affected by hydrogen sulphide test-solution, either before or after acidulation with a drop of hydrochloric acid (absence of arsenic, lead, etc.); nor by ammonium sulphide test-solution (absence of iron, aluminum, etc.). No turbidity should be produced in the solution by potassium dichromate test-solution (absence of barium). If 0.5 Cc. of silver nitrate test-solution be added to 5 Cc. of the aqueous solution (1 in 20), not more than a slight opalescence should be perceptible (limit of chloride, etc.). If 0.5 Gm. of the salt be placed upon a watch-glass, and 1 Cc. of sulphuric acid be carefully poured upon it, no effervescence should occur (absence of carbonate, oxalate, etc.); nor should any penetrating odor be perceptible, even after gentle heating (absence of butyrate, propionate, etc.); nor should the acid assume, within ten minutes, a deeper color than a pale straw-yellow (limit of readily carbonizable, organic impurities). If 1.33 Gm. of the salt, rendered anhydrous, before being weighed, by carefully drying at 110° C. (230° F.), be ignited, until most of the carbon has disappeared, and then distributed in 10 Cc. of water, it should require, for complete neutralization, not less than 9.9 Cc. of normal sulphuric acid (corresponding to at least 98.6 per cent. of the pure salt), methyl-orange being used as indicator." *U. S.* 1890.

Uses.—Strontium lactate was originally brought forward by J. V. Laborde, who found it to have a distinct diuretic action. His researches led to clinical studies of the drug by Germain Sée, Paul, Dujardin-Beaumetz, and others. It is asserted that strontium lactate is an extremely successful remedy in the treatment of *nephritis* and

chronic *albuminuria*, the urine being increased, the albumin lessened or entirely removed, and the general nutrition improved. It is stated that the action of this lactate upon the excretion of albumin is especially marked in epithelial and parenchymatous nephritis, but is much less pronounced in interstitial nephritis, and is not present when albuminuria is due to pulmonary congestion; also that it is not necessarily accompanied by an increased flow of urine, and is the result of an influence upon the tissues of the kidneys. Upon the intestinal canal the lactate is asserted to exert a very favorable influence. Strontium lactate has also been tried with alleged good results in the treatment of *rheumatism* and *gout*, it being affirmed that it increases the nitrogenous elimination and causes disappearance of the urates. *Dose*, from ten to thirty grains (0.65–2.0 Gm.) three times a day in solution.

Strontium Sulphide. *Strontii Sulphidum*. SrS. This substance has been used to some extent as a depilatory, in accordance with the following method: A powder of 2 parts strontium sulphide, 3 parts of zinc oxide, and 3 parts of powdered starch, kept dry until used, is formed into a paste with warm water and allowed to remain upon the surface from which the hair is to be removed from one to five minutes, being taken off so soon as pronounced pain or any evidences of caustic action are perceptible. The surface should then be gently but firmly scraped with a blunt edge like that of a paper knife, washed well with warm water, and treated with an emollient.

Strychnine Arsenate. *Strychnine Arsenas*. J. Russell praises this salt highly as a prompt means of getting the conjoint effects of its constituents; he employs its solution (1 in 250) hypodermically, and states the first dose as one-sixty-fourth of a grain, increased to one-fifteenth (0.001–0.004 Gm.). (*W. M. Bl.*, Sept. 1886.)

Strychnos Potatorum, L. *Chilbinj*. *Clearing Nuts*. *Indian Gum Nuts*. (Fam. Loganiaceæ.)—The nuts of this species of *Strychnos* are very largely used in some parts of India for clearing muddy water, and are stated to have found their way into American commerce. (*A. J. P.*, 1871.) The fruit is also employed by the native practitioners of Hindostan, under the name of *nirmali*, as an emetic and in *dysentery*. They do not contain strychnine. In clearing water, one of the dried nuts is rubbed hard for a short time around the inside of the earthen water pot; on settling, the water is left pure and tasteless. The seeds contain a large quantity of an albuminous principle, upon which their virtues probably depend. The tree, which grows to a very large size, produces a shining, black, one-seeded berry (that of the *nux vomica* being many-seeded). The seeds are described (*P. J.*, 1871, 44) as broadly lenticular, about half an inch in diameter and a quarter of an inch in thickness, of a dirty whitish-gray color, and covered with a thick coating of delicate appressed hairs. These are so small that the seed to the naked eye looks mealy. Under the microscope the hairs are seen to be agglutinated in bundles of from three to six, and to consist each of a single pointed cylindrical cell.

Stylophorum. *Stylophorum diphyllum* (Michx.), Nuttall. (Fam. Papaveraceæ.)—According to E. Schmidt, the root of this American plant contains *chelidonium*, with a second alkaloid closely related to, if not identical with, *chelerythrine*. (*A. J. P.*, 1888.)

Stylosanthes. *Stylosanthes biflora* (L.), B. S. P. (*S. elatior*, Swz.) (Fam. Leguminosæ.) It is asserted that this American plant has the power of relieving abdominal uterine pains during the latter months of gestation, and is also a uterine tonic during parturition. *Dose*, of the fluid-extract, from ten to twenty minims (0.6–1.3 Cc.) three times a day.

Subcutin.—This compound of paraphenolsulphuric acid with paramido-benzoic acid has been brought forward by Ritsert as non-toxic, distinctly germicidal, and locally anæsthetic. It is a white crystalline powder, soluble to the extent of 1 per cent. in cold water, and two and one-half per cent. in tepid water. For hypodermic use to this solution is added about 1 per cent. of ordinary salt. It is stated that it is especially adapted to the production of infiltration anesthesia.

Sublamine. *Hydrargyri Sulphas Ethylenediaminata*.—This substance is a white powder, soluble in water, composed of three molecules of mercuric sulphate and eight molecules of ethylenediamine, and contains about 43 per cent. of mercury. It was originally brought forward as a non-irritant germicide of exceptional penetrative power, and especially useful for the purpose of disinfecting the hands and skin; used in solution varying from 1 to 1000 up to 1 to 200. It has also been highly commended in 1 to 300 for sterilizing suture silk by boiling.

Sublamine has also been employed to some extent for the hypodermic administration of mercury; one and seven-tenths parts of it are equivalent in the mercurial to one part of the bichloride, but it is affirmed by Schuftan, when given hypodermically, to be more active than corrosive sublimate, probably because it does not coagulate albumin.

Sublimo-Phenol. *Phenolated Mercurio Chloride.* *Chloro-phenolate of Mercury.*—Colorless crystals produced by precipitation when solutions of mercuric chloride and potassium phenolate are mixed. It is easily soluble in fused phenol or boiling aqueous or alcoholic solutions of phenol. It is used in antiseptic surgery.

Succinic Acid. *Acidum Succinicum.* *Sal Succini Volatile.* *Acide succinique*, Fr. *Bernsteinsäure*, G. $\text{H}_2\text{C}_4\text{H}_4\text{O}_4$.—This acid is obtained by distilling amber. The product is an aqueous solution of succinic acid, associated with empyreumatic oil. (See *Amber and Oil of Amber*, page 1378.) By filtering the liquor the solution of the impure acid passes through, while the oil is absorbed by the paper. The acid may be purified by boiling the solution with nitric acid, diluted with twice its bulk of water, and then evaporating to crystallize: should the crystals not be colorless, the treatment with nitric acid must be repeated until they are so. Succinic acid is made artificially by the action of nitric acid on the fatty acids, and may be produced in a great many ways from various substances. Thus, it is invariably formed in small amount in the alcoholic fermentation of sugar. Desaignes obtained it more advantageously from calcium malate subjected to fermentation excited by casein. The malate was converted into calcium succinate, which was then decomposed by sulphuric acid, so as to yield succinic acid. For the details of the process for obtaining succinic acid from calcium malate, see the paper of E. J. Kohl, in *A. J. P.*, vol. xxvii. July. Succinic acid, when pure, is in white, transparent crystals, having no odor and a somewhat acid taste. It dissolves in five times its weight

of cold and twice its weight of boiling water. It is less soluble in alcohol, and very sparingly so in ether. Nitric acid is without action on it. It melts at 182°C . (359.6°F .), and boils without alteration at 235°C . (455°F .). It sublimes, however, at a much lower temperature. According to Wackenroder, it is sometimes adulterated with tartaric acid soaked in oil of amber. Succinic acid, though formerly official, is at present seldom used in medicine. It has been ascertained to be a product of vital action, having been detected by Heintz in the colorless liquid found in hydatid cysts of the liver. (See *J. P. C.*, Sept. 1850.) One of its salts, ammonium succinate, $(\text{NH}_4)_2\text{C}_4\text{H}_4\text{O}_4$, made by supersaturating succinic acid with ammonia, evaporating and crystallizing, has been used with great alleged success in *delirium tremens*. This salt is occasionally used as a precipitant of ferric oxide.

For a description of sodium succinate, see page 1652.

Sucramine.—This substance, which has been exploited in France as a new sweetening agent, is said to be simply the ammonium salt of saccharin.

Sulfosote. *Potassium creosotic-sulphonate*, or a mixture of *guaiacol- and cresol-sulphonates of potassium*.—Under its proprietary name, sulfosote is supplied in the form of a syrup, of which the dose is said to be, for the adult, three fluidrachms (11.25 Cc.). It has been used in various forms of pulmonic disease for the treatment of which creosote is advisable.

Sulphaldehyde is made by the action of hydrogen sulphide upon acetaldehyde in aqueous solution. An oil is obtained which solidifies at low temperatures. According to Lusini (*Nouv. Rem.*, 1890), this substance acts on the lower animals as a powerful hypnotic.

Sulphaminol. $\text{C}_6\text{H}_4 < \begin{smallmatrix} \text{S}_2 \\ \text{NH} \end{smallmatrix} > \text{C}_6\text{H}_5\text{OH}$. *Thiooxydiphenylamine*.—This compound is made by the action of sulphur upon the salt of metaoxydiphenylamine. It is a pale yellow powder free from odor and taste, readily soluble in alkalies, more difficultly so in alkaline carbonates, quite insoluble in water. When heated it turns brown, and melts at 155°C . (311°F .). It is asserted that this substance is harmless (see a paper by Kober, *Journ. de Méd.*, Sept. 1890), and that when taken internally it is split up in the organism into oxydiphenylamine and sulphuric acid compounds. It has been used as a substitute for iodoform, having the advantage of being odorless. Various compound solutions of it have been employed as local applications to the mucous membranes of the nose and larynx, such as *sulphaminol menthol*, *s. creosote*, *s. guaiacol*, *s. eucalyptol*. Internally, it has been given in doses of from four to five grains (0.26–0.32 Gm.); externally, it may be used in powder or oily solutions.

Sulphites, Bisulphites, Thiosulphates.—These salts were introduced into medicine because of their extraordinary hostility, through their acid ingredient, to the lower forms, whether of vegetable or animal life. Microscopic plants and animals cannot exist in the presence of sulphurous acid, and, as its salts are easily decomposed, with the liberation of the acid, they are capable of exercising the same destructive influence. In parasitic diseases, such as *scabies*, *porrigo*, *prurigo senilis*, different forms of *ringworm*, *pityriasis versicolor*, the *sore mouth* or *thrush of infants*, etc., the local use of these remedies is often very

efficient. In cases of *fermentative dyspepsia* the sulphites may be of value in checking the changes of the food. At one time it was supposed that they would be of value as germicides in *zymotic disease*, but theory indicates that unless given in poisonous doses they could have no influence upon disease germs in the system, and clinical experience has abundantly shown that they are valueless in infectious diseases.

Of the *sulphites*, those which have been employed are *sodium*, *potassium*, *ammonium*, *magnesium*, and *calcium sulphites*. *Sodium sulphite* is official. (See page 1157.)

Ammonium sulphite may be prepared by passing sulphurous acid to saturation into a solution of ammonium carbonate, and evaporating the solution rapidly, avoiding as far as possible exposure to the air. The sulphites of magnesium and calcium whose carbonates are insoluble may be prepared more advantageously by double decomposition, but calcium sulphite may be prepared by using lime water for the saturation of the sulphurous acid. Whenever evaporation is employed, it should be carefully conducted so as not to drive off the acid, and with as little exposure to the air as possible, as the sulphites in solution are strongly disposed to pass into sulphates. Even in the solid state they slowly undergo the same change, and should therefore be kept, as far as can be conveniently done, excluded from the air. The sulphites in general have a mild sulphurous taste, and on exposure to heat, or with the addition of an acid, emit the characteristic odor of sulphurous acid. They are distinguishable from the *thiosulphates* or *hyposulphites* by not depositing sulphur on the addition of diluted sulphuric acid to their solutions. As the efficiency of the sulphites is ascribable to their acid, they may be used indiscriminately, one being preferred to another according to solubility, or other property affecting the convenience of exhibition.

Sodium, *magnesium*, and *potassium sulphites* have been fully described, and the remarks in reference to their therapeutical application may be considered as applicable to the others. *Ammonium sulphite*, $(\text{NH}_4)_2\text{SO}_3$, has an acid sulphurous taste, at first deliquesces in the air, and afterwards dries, gradually being converted into the sulphate by the absorption of oxygen. It is soluble in its weight of cold, and in less than its weight of boiling water. It decrepitates with heat, losing a part of its ammonia, and then sublimes as an acid sulphite. *Calcium sulphite*, CaSO_3 , is a white powder, and distinguished by its difficult solubility, requiring 800 parts of water for solution. An excess of acid renders it more soluble, and from its hot saturated solution it is deposited, on cooling the liquid, in hexagonal needles.

The influence of these salts on the system in health is feeble. Six drachms have been taken in twenty-four hours, without injury. When taken internally, they are absorbed, and partly eliminated unchanged with the urine, partly changed by the absorption of oxygen into sulphates, as happens on exposure out of the body, the urine at first containing a sulphite, and after twenty-four hours a sulphate. From the largest doses of the sulphites only a laxative effect and an increased secretion of the urine are obtained. Their long-continued use is said to prove injurious, by inducing debility and anæmia. From fifteen grains to a drachm (1.0–3.0 Gm.) may be given, so repeated as to amount to from two drachms to an ounce in twenty-four hours. As almost all acids

decompose the sulphites, they should not be administered with any acid substance. Should the bowels be disturbed, a little of some opiate may be given. For external use, one part of the salt employed may be dissolved in from five to ten parts of water.

Acid Sulphites (Bisulphites).—These are quite as efficient as the sulphites, probably more so, in consequence of their relatively greater proportion of acid. They might be and probably are used indiscriminately with the sulphites, as, in the preparation of the latter by the direct union of their constituents, the sulphurous acid may readily be used in excess, and thus give rise to the bisulphite. Indeed, Berzelius states that the salt formed by passing sulphurous acid through a solution of sodium carbonate until the liquid shall sensibly redden litmus paper, is really sodium bisulphite, and that the sulphite may be prepared by adding to this salt a quantity of soda equal to that already contained in it. The bisulphites generally may be prepared by passing sulphurous acid in excess through the alkaline solution, or through the solution of a sulphite already formed. (See also *P. J.*, 1872, 844.) They may be distinguished from the sulphites by their strong odor of sulphurous acid and by the fact that they are neutral or faintly acid to test paper, while the latter salts have a feeble alkaline reaction. They may be given for the same purposes and in the same dose and by the same method of administration as the sulphites. Some years since (*P. J.*, 1867), W. Lascelles Scott called attention to the *calcium bisulphite* as a very valuable preservative; but his statements have not led to the practical use of the drug.

Thiosulphates (Hyposulphites or Sulphosulphates).—These may be considered as absolutely identical for therapeutic purposes with the sulphites, as, when they undergo decomposition, sulphurous acid is eliminated. The hyposulphites consist of bases combined with an acid, which, in the free state, would be $\text{H}_2\text{S}_2\text{O}_3$, but which, when liberated, separates into sulphurous acid and sulphur. They are prepared by boiling a sulphite or bisulphite in solution with sulphur, as in the example of sodium thiosulphate,

or are made on a larger scale by passing sulphur dioxide into the calcium sulphide liquor of the alkali waste, whereby calcium thiosulphate is formed. This may then be changed into the sodium salt by the action of sodium sulphate, yielding sodium thiosulphate and calcium sulphate. The chief advantage possessed by the thiosulphates or hyposulphites is that they are less disposed than the sulphites to change into sulphates by the absorption of oxygen. They may be recognized by the deposition of sulphur when an acid is added to their solutions. They are freely soluble in water, even the calcium and magnesium thiosulphates. They may be used for the same purposes and in the same doses as the sulphites, and administered in the same way.

Sulphoricinic Acid.—This is made by the action of from 30 to 40 per cent. sulphuric acid upon castor oil at a temperature not exceeding 50°C . (122°F .), care being taken to avoid the evolution of sulphur dioxide. On the addition of water, sulphoricinic acid with unchanged oil separates in an oily layer from the aqueous solution of acid below. This substance is a powerful local irritant. Berlioz states that the acid and its soluble salts are actively antiseptic and deodorizant; useful as

a local application in *ozæna* and other affections. (S. M., March 11, 1891.) *Sodium sulphoricinate*, $C_{12}H_{22}O_2OSO_3$, forms a brown liquid, miscible with water and alcohol, with a feebly alkaline reaction. It has the power of dissolving powerful antiseptic substances as phosphorus, iodine, phenol, resorcinol, naphthalene, and other substances making strongly antiseptic solutions. Of these preparations the only one of importance is the *phenol sodium-sulphoricinicum*, often incorrectly known as *phenol sulphoricinicum*.

Phenolum Natrio-sulphoricinicum (*phenol sulphoricinate*) is a yellowish syrupy liquid, containing 20 per cent. of phenol and 80 per cent. of sodium sulphoricinate. The liquid itself mixes in all proportions with water, and has been especially commended as a local application in various diseases of the skin and in tubercular and other ulcerations of the mucous membranes. First recommended by T. Heryng (Th. M., 1896) as a local caustic application to *papilloma* and *ulcers* in the nasal and laryngeal passages, or diluted in various forms of chronic inflammation of the mucous membrane of the nose and larynx. These statements have been confirmed by various laryngologists. Prezedborski finds it of very great service both in *rhinitis atrophica* and *hypertrophica*. Berlioz (B. G. T., 1890) especially recommends it in *diphtheria*. The 20 per cent. aqueous solution is to be applied locally to the throat four times a day and once or twice in the night. (S. M., 1892.) *Naphthol sulphoricinate*, *sabul sulphoricinate*, and *creosote sulphoricinate* have also been made and used as local agents.

Sulphosalicylic Acid. *Salicyl-sulphonic Acid*. $C_6H_5SO_3H.OH.CO_2H$.—Made by acting upon salicylic acid with strong sulphuric acid. It is in the form of white acicular crystals, soluble in water and alcohol. Sulphosalicylic acid is used, like sodium salicylate, in rheumatism, but its chief value lies in its use as a reagent to detect the presence of proteids of all kinds. Egg-albumin (1 in 12,500) can be detected by this reagent, forming a dense white precipitate which is not redissolved on boiling. It is used to detect albumin, peptones, globulins and fibrin. Albumoses and peptones redissolve when boiled but again separate on cooling.

Sweet Pellitory.—The root of *Tanacetum umbelliferum*, Boiss. (Fam. Compositæ), of India, according to David Hooper, contains pyrethrine in minute proportions with fat and wax, an organic acid which is a pigment, glucose, and inulin. (P. J., xxi. 1890.)

Swietenia. *Swietenia febrifuga*, Roxb. (*Soy-mida febrifuga*, Juss.) *Rohun Bark*. (Fam. Meliaceæ).—The bark of this East Indian tree is said to be much used as an antiperiodic in half drachm (2 Gm.) doses.

Swietenia Mahagoni, Jacq., or *mahogany tree*, which grows in the West Indies and other parts of tropical America, has also a bitter, astringent bark, containing catechin (Bull. Soc. Chim. Paris, xxiv. 118). The bark of *S. senegalensis*, Desv. (*Khaya senegalensis*, A. Juss.), *Juribali bark*, is used on the coast of Africa in the cure of *intermittents*, and Caventou extracted an alkaloid from it. (Am. J. M. S., N. S., xx. 168.)

Sycese.—This name has been applied to saccharin and also to preparations of saccharin. (See *Benzosulphimidum*, p. 234.)

Symphorol. *Symphorol*. *Sodium, Lithium, or Strontium Caffeine-sulphonates*.—The name symphorol is applied to either of the salts above men-

tioned. They are colorless, odorless, bitter powders. The sodium salt is used as a diuretic, the lithium salt in *gout* and *rheumatism*, and the strontium salt in *Bright's disease*.

Symphytum. *Symphytum officinale*, L. *Comfrey*. *Radix Symphiti*. *Radix Consolidæ Majoris*. *Consoude*, Fr. *Schwarzwurzel*, *Beimwurzel*, G.—A perennial European plant often cultivated. Its root is spindle-shaped, branched, often more than an inch thick and a foot long, externally smooth and blackish, internally white, fleshy, and juicy. By drying it becomes wrinkled, of a firm, horny consistence, and of a dark color within. It is almost inodorous, and has a mucilaginous, feebly astringent taste. It contains mucilage in great abundance (according to Lewis, more than *althæa* root) and a little tannin. It was formerly highly esteemed as a vulnerary. Its virtues are those of a demulcent, like marshmallow, and it is used domestically in *chronic catarrhs*, *consumption*, and other lung diseases.

Symplocos. *Symplocos racemosa*, Roxb. (Fam. *Styracææ*).—The bark of this East Indian tree is said to be a mild astringent, and especially useful in *menorrhagia*. (P. J., Sept. 24, 1881.)

Synanthrose. *Lævulin*. $C_6H_{10}O_5$.—This is a carbohydrate, isomeric with inulin, discovered by O. Popp in *Helianthus tuberosus*, L. (Fam. *Compositæ*.) For details, see Tollens, *Kohlenhydrate*, 198.

Syringa. *Syringa vulgaris*, L. *Common Lilac*. (Fam. *Oleaceæ*).—The leaves and fruit of this common garden plant have a bitter and somewhat acrid taste, and have been used as tonics and antiperiodics. Petroz and Robinet found in the fruit a sweet and a bitter principle. The latter was afterwards obtained pure by Meillet, who gave it the name of *lilacin*, and by Bernays, who called it *syringin*. It has been investigated by Kromayer (A. Pharm. (2), 113, 19), who established its glucosidal character, gave it the formula $C_{17}H_{24}O_9 + H_2O$, and showed its identity with the *ligustrin* of Polex. It forms long white stellate needles, which are tasteless, easily soluble in hot water and alcohol, insoluble in ether. The crystals become anhydrous at 115° C. (239° F.), and fuse at 212° C. (413.6° F.). On heating with dilute acids it breaks up into *syringenin*, $C_{11}H_{14}O_4$, and a fermentable glucose. The *syringenin* (which has been recognized as *oxymethyl coniferin*) is a light rose-red amorphous mass, soluble in alcohol, insoluble in water and ether.

Syrup of Ferrous Bromide. *Syrupus Ferri Bromidi*, U. S. 1880. *Syrup of Bromide of Iron*. "A syrupy liquid containing 10 per cent. of Ferrous Bromide. Iron, in the form of fine wire, and cut into small pieces, *thirty parts* [or one and a half ounces av.]; Bromine, *seventy-five parts* [or nine fluidrachms]; Sugar, in coarse powder, *six hundred parts* [or twenty-eight ounces av.]; Distilled Water, *a sufficient quantity*, to make *one thousand parts* [or about two pints]. Introduce the Iron into a flask of thin glass of suitable capacity, add to it *two hundred parts* [or nine fluidounces] of Distilled Water and afterwards the Bromine. Shake the mixture occasionally, until the reaction ceases and the solution has acquired a green color and has lost the odor of Bromine. Place the Sugar in a porcelain capsule and filter the solution of bromide of iron into the Sugar. Stir the mixture with a porcelain or wooden spatula, heat it to the boiling point on a sand-bath, and, having strained the Syrup through linen into a tared bottle, add

enough Distilled Water to make the product weigh *one thousand parts* [or measure two pints]. Lastly, shake the bottle and transfer its contents to small vials, which should be completely filled, securely corked, and kept in a place not accessible to daylight." *U. S.* 1880. Although this syrup is not so sensitive to the oxidizing action of the air as syrup of ferrous iodide, it is preferable to filter the solution into hot syrup instead of into sugar in an open capsule. It is "a transparent, pale green liquid, odorless, having a sweet, strongly ferruginous taste, and a neutral reaction. With test-solution of ferrieyanide of potassium it yields a blue precipitate. If a little carbon disulphide be added to the Syrup, then a few drops of chlorine water, and the whole agitated, the disulphide will separate with a yellow or brown color. It should not deposit a sediment on keeping, and should not tinge gelatinized starch yellow (absence of free bromine). 5.39 Gm. of the Syrup should require for complete precipitation 50 Cc. of the volumetric solution of nitrate of silver (corresponding to 10 per cent. of ferrous bromide)." *U. S.* 1880. Ferrous bromide has been recommended as a sedative chalybeate tonic, and has been especially praised by Jacob Da Costa in *chorea*. In an extended trial of it by H. C. Wood, it failed entirely to be of service. It is not an eligible chalybeate. *Dose*, of the syrup, from one-half to one fluidrachm (1.8–3.75 Cc.), equal to about four to eight grains of the bromide.

Tacamahac. *Tacamahaca*.—The resinous substance commonly known by this name is supposed to be derived from *Bursera tomentosa*, Triana (*Fagara octandra*, L., *Elaphrium tomentosum*, Jacq., *Amyris tomentosa*, Spreng.), a tree of considerable size, of the fam. Burseraceæ, growing in the island of Curaçoa and in Venezuela. The juice exudes spontaneously, and hardens on exposure. As brought into the market, it is in irregularly shaped pieces of various sizes, some not larger than a mustard seed, others as much as an inch or two in diameter. The color is usually light yellowish or reddish-brown, but in the larger masses is more or less diversified. The pieces are in general translucent, though frequently covered with powder upon their surface, so as to render them apparently opaque. They are heavier than water, brittle, and pulverizable, yielding a pale yellow powder. Their odor is resinous and agreeable, their taste bitter, balsamic, and somewhat acrid. Exposed to heat, they melt and exhale a stronger odor. Tacamahac is partially soluble in alcohol, and completely so in ether and the fixed oils. It consists of resin with a little volatile oil.

Another variety is obtained from the East Indies, and called *tacamahaca orientale*, or *tacamahaca in testis*. It is supposed to be derived from *Calophyllum inophyllum*, L., and comes into the market in gourd shells covered with rush leaves. It is of a pale yellow color inclining to green, slightly translucent, soft, and adhesive, of an agreeable odor, and an aromatic bitterish taste. It is at present very rare in commerce. The tree which yields this resin produces a drupe, about as large as a plum, from the seeds of which 50 per cent. of a greenish-yellow fixed oil is obtained by expression, which is used in India for lamps, and as a local application in the *itch*. (*J. P. C.*, 1861, 23.) Guibourt describes several other varieties of tacamahac, which, however, are little known. Among them is a soft, adhesive, dark green oleoresin (*J. P. C.*, 3e sér., xxiv. 396), said to be procured from the *Calophyllum Tacamahaca*,

Willd., growing in the islands of Réunion and Madagascar. (See also Pennetier, *Matières Premières*, 642.)

Tacamahac was formerly highly esteemed as an internal remedy, but is now used only in ointments and plasters. Its properties are analogous to those of the turpentine. It is sometimes used as incense.

Tachia. *Tachia guyanensis*.—The root of this tree (Fam. Gentianacæ) is used under the name of *Caferana*, in Brazil, as an antiperiodic and tonic. According to Peckoldt it contains an organic crystalline substance, *caferanine*. (See *Merck's Bericht*, 1889; also *Ber. d. Chem. Ges.*, 1899, No. 7.)

Taka Diastase.—This ferment is formed by the action of a fungus (*Moyashi*; *Aspergillus oryzae*, Cohn, *Eurotium oryzae*, Ahlburg; for description, see *A. J. P.*, 1898, 137) upon steamed rice, and is used in Japan, where it is known by the name of *koji*, in the preparation of the national intoxicating beverage *sake*. It has also been employed to act upon maize in the making of whisky. It is a yellowish-white, highly hygroscopic powder, almost tasteless, freely soluble in water. It is capable, under proper conditions, of converting one hundred times its weight of starch in ten minutes into glucose. Its action resembles very closely that of saliva; according to the experiments of Julius Friedenwald (*N. Y. M. J.*, 1897), it not only aids in the digestion of the starches, but serves the other function of the saliva in stimulating the gastric secretion, and thereby promoting the proteid digestion. It would seem, therefore, to be especially indicated as an artificial digestant in cases in which there is a deficiency of saliva.

There is much clinical evidence on record as to its value in all cases in which there is loss of power of digesting starches, and the correctness of Armstrong's assertion (*Liverpool Med.-Chir. Journ.*, 1897), that it is especially valuable in gouty persons in whom the starch digestion is often feeble, would seem to be well founded. In Friedenwald's experiments with test breakfasts it was found not to affect normal gastric digestion, and to be of very little value in pure *nervous dyspepsia*. In cases of *gastric catarrh*, with sub-acidity, it appeared to have a tendency to increase the acidity of the gastric juices and to promote the digestion of starches. Its greatest applicability, however, was found to be in cases of hyper-acidity, in which it is stated to diminish the excess of acid and increase gastric peristalsis. It should be given in the middle of the meal, in doses of from five to ten grains (0.32–0.65 Gm.), in capsules; or, after the meal, in slightly alkaline solution.

Tanacetum. *U. S.* 1890. *Tansy*.—Under this name the *U. S. Pharmacopœia* formerly recognized the tops and leaves of the *Tanacetum vulgare*, L., a perennial herbaceous plant rising two or three feet in height, which is cultivated in our gardens, although growing wild in the roads and in old fields. It was originally introduced from Europe. It is in flower from July to September.

Tansy was officially described as follows: "Leaves about 15 Cm. [six inches] long; bipinnatifid, the segments oblong, obtuse, serrate or incised, smooth, dark green, and glandular; flower-heads corymbose, with an imbricated involucre, a convex, naked receptacle, and numerous yellow, tubular florets." *U. S.* 1890. The odor is strong, peculiar, and fragrant, but much diminished by drying; the taste is warm, bitter, somewhat acrid,

and aromatic. These properties are imparted to water and alcohol. According to Leppig (*In. Dis.*, Dorpat, 1882), both the flowers and the leaves contain the following constituents: *tanacetin*, tannic acid (*tanacetum-tannic acid*), traces of gallic acid, volatile oil, a wax-like substance, albuminoids, tartaric, citric, and malic acids, traces of oxalic acid, a lavogyrate sugar, resin, metarabic acid, pararabin, and woody fibre. Of these the most important are the bitter principle *tanacetin*, to which Leppig gives the formula $C_{11}H_{18}O_4$, a compound first discovered by Homolle (1845), the tannic acid, to which he gives the formula $C_{23}H_{29}O_{31}$, and the volatile oil, of which the flowers yielded 1.49 per cent. and the leaves 0.66 per cent. The *tanacetic acid* of Peschier he considers to be impure malic acid, an opinion shared by Husemann. (*Pflanzenstoffe*, 2d ed., 1884, p. 1531.) The bitter principle *tanacetin* forms a very hygroscopic, brownish, amorphous mass, easily soluble in alcohol and in water, insoluble in ether. It possesses a taste at first characteristically bitter like willow bark, and then cooling and caustic. The essential oil was investigated by Bruylants (*Ber. d. Chem. Ges.*, xl. 449), according to whom it consisted of a terpene, $C_{10}H_{16}$, boiling at from 155° to 160° C. (311° – 320° F.), of which 1 per cent. only is present, an aldehyde, $C_{10}H_{16}O$, boiling at from 195° to 196° C. (383° – 384.8° F.), of which 70 per cent. was obtained, and an alcohol (borneol), $C_{10}H_{18}O$, boiling at from 203° to 205° C. (397.4 – 401° F.), of which 26 per cent. was present. Semmler (*Ber. d. Chem. Ges.*, xxv. 3343, 3352, 3513) has specially investigated the constituent boiling at 195° C. (383° F.), and having the composition $C_{10}H_{16}O$. He finds it to be not an aldehyde, but a ketone, and calls it *tanacetone*. It is identical with the ketone found in sage oil, wormwood oil, and thuja oil. As it was first identified in this last-named oil by Wallach, and named by him *thujone*, this name is now applied to it to the exclusion of the other. (See also *Schim. Rep.*, April, 1893, and April, 1897; and Gildemeister and Hoffmann, *Aetherische Oele*.) Tansy adds to the medicinal properties of the aromatic bitters those of an irritant narcotic. It has been recommended in *intermittents*, *hysteria*, and *amenorrhœa*, but in this country is little employed in regular practice. The seeds are said to be most effectual as a vermifuge. The dose of the powder is from thirty grains to a drachm (2.0–3.0 Gm.) two or three times a day; but the infusion is more frequently administered. Tansy has been used to a considerable extent as a domestic abortifacient, but is not only very uncertain but also very dangerous in its action, and has in various cases produced death. The symptoms caused by it have been abdominal pain, vomiting, violent epileptic convulsions often followed by profound coma, dilated pupils, great disturbances of respiration, frequent and feeble pulse, and death, which has been said to be from heart failure, but is probably the outcome of a paralytic asphyxia. The minimum fatal dose can scarcely be considered to have been positively ascertained, but a fluidrachm (3.75 Cc.) of the oil is said to have caused death, although recovery in one case occurred after taking half a fluidounce. Tansy tea has also caused death. (For cases, see *Am. J. M. S.*, xvi., xxiii., xxiv.; *J. P. O.*, April, 1870; also H. C. Wood's *Therapeutics*.) Post-mortems have been reported in which no inflammation of the gastro-intestinal mucous membranes could be discovered.

Tanghinia. *Ordeal Bean of Madagascar.*—*Tanghinia venenifera*, Poir. (*Cerbera Tanghin*, Hook.) (Fam. Apocynaceæ), has been investigated, and, according to C. E. Quinquaud, is both a respiratory and a cardiac poison. (*C. R. A. S.*, cl. 534. See also *T. G.*, vol. ii. 610.) The active principle, *tanghinin*, occurs in colorless lustrous scales, efflorescing in the air, having a bitter and sharp taste, soluble in alcohol, ether, and acetic acid.

Tang-kui or Man-mu.—Under these names from time immemorial there has been used in China as an emmenagogue the root of an araliaceous plant, the fluidextract of which has been placed upon the market by Merck under the name of *eumenol*. It has been recommended by various clinicians in the treatment of *dysmenorrhœa* and *amenorrhœa*, given in doses of one to two fluidrachms (3.75–7.5 Cc.) three times a day during the menstrual week. Bufalini, having searched in vain for an active alkaloid, believes that the activity of the substance depends upon an ethereal oil.

Tannalbin. *Tannin Albuminate.*—This compound, suggested by Gottlieb, is made by adding to ten parts of a 10 per cent. solution of albumin, six and a half parts of a 10 per cent. solution of tannin; the precipitate is collected, washed, pressed, and dried by exposure to heat (about 110° C., 230° F.) for six hours. It contains about one-half its weight of tannin. It is a light brown powder, insoluble in water and in the gastric juice, tasteless, odorless, and not at all irritant to the mucous membranes. As an astringent it is very feeble, but, as the tannic acid is probably liberated in the intestines, it is a valuable remedy in the treatment of *chronic diarrhœa* dependent upon intestinal relaxation, and has even been used with asserted satisfaction when there were intestinal catarrh and ulceration. It does not disturb the digestion, indeed, has been highly commended in *gastric catarrh* with excessive secretion of mucus. It has also been found useful in *chronic albuminuria*, especially in lessening the amount of albumin in the urine. *Dose*, from fifteen to thirty grains (1–2 Gm.), three to six times a day, in capsule or powder.

Tannalum. *Tannal.* *Basic Aluminum Tannate.* $Al(OH)_2(C_{14}H_9O_9) + 5H_2O$.—This is a brownish-yellow powder, insoluble in water, which has been especially commended by Heymann as a mild, astringent, non-irritant substance, to be used as a dusting powder or by insufflation in diseases of the nasal and laryngeal mucous membranes. By the action of tartaric acid it becomes converted into the so-called *soluble tannal*, $Al(C_4H_4O_6)(C_{14}H_9O_9) + 3H_2O$, also used locally.

Tannigen. *Diacetyl Tannic Acid.* $C_{14}H_8(COCH_3)_2O_9$.—This compound, which is prepared by the action of acetic anhydride or acetyl chloride upon tannin, is the diacetic ester of tannic acid. It is a yellowish-gray, tasteless and odorless, slightly hygroscopic powder, which can be heated to 180° C. (356° F.), without alteration; insoluble in cold water, readily soluble in alcohol, dissolving in diluted solution of sodium phosphate, soda, or borax, with the production of a yellowish-brown color. It has been used as a mild astringent in *chronic diarrhœas*, especially in such as often accompany *phthisis*, and as a local application by insufflation in *chronic rhinitis* and *laryngitis*. *Dose*, from ten to fifteen grains (0.65–1.0 Gm.) three or four times a day, in capsules; to children it may be given spread on bread and butter.

Tannochrom is found in commerce as a gray insoluble powder containing fifty per cent. of a compound of chromium bitannate and resorcinol; a fifty per cent. solution is also used which is miscible with water, alcohol and glycerin. The powder is used in the treatment of *eczema* and other skin diseases, and the liquid in one-fourth to one-half per cent. solution in *gonorrhœa*.

Tannocol. Gelatin-tannate.—This is a tasteless, odorless powder, containing about 50 per cent. of tannic acid, having the same therapeutic properties and applications as tannalbin. It is claimed by Rosenheim that it is superior to that substance in being cheaper, of greater constancy of constitution, and less apt to be affected by the gastric juices. In the intestines it is decomposed by the alkaline secretions and tannic acid is liberated. *Dose*, fifteen to thirty grains (1-2 Gm.).

Tannoform. Methylene Ditannin. $\text{CH}_2(\text{C}_{14}\text{H}_9\text{O}_9)_2$.—A new class of bodies has been prepared by Merck which are termed tannoforms, and which consist of combinations between the various characteristic tannins and formaldehyde. These bodies are formed by adding a solution of formaldehyde gas to a purified plant extract containing the plant tannin in the presence of hydrochloric acid. The further nomenclature of the tannoforms depends upon the name of the plant from which the particular tannin is derived.

The condensation product of gallotannic acid and formaldehyde, which is termed simply tannoform, is made by dissolving five grammes of tannin in about fifteen kilogrammes of hot water, adding three kilogrammes of 30 per cent. formaldehyde, and then adding concentrated hydrochloric acid until no further precipitate is thrown down. This requires about twelve to fifteen kilogrammes of acid. The precipitate is then washed with water and dried at a low temperature.

Tannoform occurs as a light pinkish-white powder which decomposes at about 230°C . (446°F). It is dissolved by alcohol and is insoluble in all the usual organic solvents; but is soluble in diluted ammonia, sodium or potassium hydroxide solutions, giving a brownish-red solution, from which it is again precipitated upon the addition of an acid. When warmed with concentrated sulphuric acid it dissolves with a brown color, turning on further heating to green, and then to blue. This green or blue solution gives a blue color with alcohol, which on standing some time turns to a wine-red, and on dilution with soda solution to a grass-green color. It has been chiefly used as a local remedy in the treatment of *eczema*, *bed sores*, *local hyperidroses*, *chancres*, etc. Von Oefele recommends it especially in *pruritus vaginæ*. Tannoform has also been commended as an external remedy in various affections of the skin with discharges, and in excessive sweating. In cases of night sweats the trunk should be bathed with alcohol and then a powder consisting of one part of tannoform and two parts of talc, should be well rubbed into the skin. In *hyperidrosis of the feet* it is stated that if for eight days, at bedtime, after a foot bath, powder of tannoform and talc (1 to 2) be well rubbed into the feet and between the toes, a most pronounced effect will be produced and will last for many weeks. It may be used as a dusting powder, or often with advantage mixed with starch.

It is stated that tannoform is decomposed in the intestines by the pancreatic juices, and acts as an astringent through its tannic acid, and as an antiseptic through its formaldehyde. It has

been used with alleged good result in acute and chronic *enteritis* and other forms of *diarrhœa*, in doses of from five to fifteen grains (0.32-1.0 Gm.), in capsule, from three to six times a day.

Tannoguaiaform is a compound of tannic acid, guaiacol and formaldehyde. It is odorless and tasteless and has been recommended as an intestinal astringent and antiseptic particularly suited to the treatment of intestinal tuberculosis, as it probably liberates formaldehyde in the intestines. Care should be used in prescribing it. *Dose*, eight to fifteen grains (0.5-1.0 Gm.).

Tannon.—**Tannopin**, $(\text{CH}_2)_6\text{N}_4(\text{C}_{14}\text{H}_9\text{O}_9)_3$, is a condensation product of tannin and hexamethylenetetramine. It is a light brown, tasteless and odorless, non-hygroscopic powder, insoluble in water, weak acids, spirit, and ether, but dissolving slowly in dilute alkaline solution. It has been used by Schreiber (*D. M. W.*, 1897) in *diarrhœa* in doses of fifteen grains (1.0 Gm.) from three to four times a day.

Tapioca.—Under this name the U. S. P. formerly recognized the fecula obtained from *Manihot Manihot* (L.), Lyons (*Jatropha Manihot*, L., *Janipha Manihot*, H. B. K., *Manihot utilisima*, Pohl, B. & T. 235), the *cassava* plant or *manioc* of the West Indies, the *mandioca* or *tapioca* of Brazil. It is a shrub belonging to the Euphorbiaceæ, about six or eight feet high, with a very large, white, fleshy, tuberous root, which often weighs thirty pounds. The stem is round, jointed, and furnished at its upper part with alternate petiolate leaves, deeply divided into three, five, or seven oval-lanceolate, very acute lobes, which are somewhat wavy upon their borders, deep green on their upper surface, glaucous and whitish beneath. The flowers are in axillary racemes.

The manihot plant is a native of South America, and is cultivated extensively in the West Indies, Brazil, and other parts of tropical America, and in Liberia, for the sake of its root, which is much employed as an article of food. It can also be grown successfully in Florida and other Southern States. (See *Forty-fourth Bulletin U. S. Dept. Agriculture*.) The plant is propagated by cuttings. It is of quick growth, and the root arrives at perfection in about eight months. There are two chief varieties, but it is said that in Brazil as many as thirty different forms of the plant are recognized by cultivators. The root of the *sweet cassava* may be eaten with impunity; that of the *bitter*, which is the most extensively cultivated, abounds in an acrid, milky juice, which renders it highly poisonous if eaten in the recent state. Henry and Boutron Chalaral affirm that the bitter cassava contains hydrocyanic acid (*J. P. C.*, xxii. 119), but Peckoldt claims that its poisonous effects are due to *manihotoxine* (*Ph. Rund.*, iv. 1890). Both varieties contain a large proportion of starch. The root is prepared for use by washing, scraping, and grating or grinding it into a pulp, which, in the bitter variety, is submitted to pressure so as to separate the deleterious juice. It is dried, and in the state of meal or powder is made into bread, cakes, or puddings. As the poisonous principle is volatile, the portion which may have remained in the meal is entirely dissipated by the heat employed in cooking. The preparation denominated tapioca among us is obtained from the expressed juice. This, upon standing, deposits a powder, which, after repeated washings with cold water, is nearly pure starch. It is dried by exposure to heat, which renders it partially soluble in cold water, and

enables it to assume its characteristic consistence. When dried without heat, it is pulverulent, and closely resembles the fecula of arrow root. In Demerara, as we are told by Pagot, the manioc juice, after having been deprived of injurious properties by boiling, is used as a sauce. (*P. J.*, 1873.)

The preparation of tapioca in Malacca is thus described by James Collins: The fresh root-stocks are thoroughly washed in tubs in a constant stream of water by scantily clad Chinese, and then peeled like turnips; they are then sliced in one machine and pulped in another, the pulp being removed in cane baskets to large wooden frames, with calico bottoms; a powerful stream of water is allowed to fall upon the pulp, a sifting motion being communicated to the strainer; as the starch is washed out, it is received into inclined troughs, and, while in a state of suspension, run into settling vats. There it is stirred and washed, and, while moist, it is removed to the drying room. Two kinds of tapioca are prepared. The flour is made by heating slightly by fires placed underneath; it is constantly stirred, and turned over with iron shovels, to prevent agglutination and insure equal drying. Granular tapioca is made as follows. A long range of qualies, or small, shallow iron pans, are slightly tilted forward on ledges of brickwork, and heated with a wood fire. Each operator has a qualie and fire to himself. Taking a quantity of damp starch, he stirs it round and round with an iron shovel, and the heat is sufficient to cause the tapioca to become agglutinated together in small masses, and coated with dextrin. The drying is done with great skill, and with an open fire. (*C. D.*, 1884.) Tapioca is also made at present on a large scale in Malacca with steam apparatus.

Tapioca is in irregular, hard, white, rough grains, possessing little taste, partially soluble in cold water, and affording a fine blue color when iodine is added to its filtered solution. The partial solubility in cold water is owing to the rupture of the starch granules by heat. Examined under the microscope, the granules appear partly broken, partly entire. The latter are muller-shaped, about the two-thousandth of an inch in diameter, more uniform in size than the granules of most other varieties of fecula, with a distinct hilum, which is surrounded by rings, and cracks in a stellate manner. *Tapioca meal*, called sometimes *Brazilian arrow root*, and by the French *moussache*, is the fecula dried without heat. Its granules are identical with those already described. Being nutritious, and at the same time easy of digestion and destitute of irritating properties, tapioca forms an excellent diet for the sick and convalescent. It is prepared for use by boiling it in water. Lemon juice and sugar are usually grateful additions, and in *low states of disease* or cases of *debility* it may be impregnated with wine and nutmeg or other aromatic.

A facitious tapioca is found in commerce, consisting of very small, smooth, spherical grains, and supposed to be prepared from potato starch. It is sold under the name of *pearl tapioca*.

Cassaripe is the thickened gum obtained from the root of the bitter cassava, which is said to be innocuous and so actively antiseptic as to be habitually used in Brazil for the preservation of meat. According to S. D. Risley (*Phila. Med. Journ.*, 1899), the 10 per cent. ointment of cassaripe is useful in *suppurating conjunctivitis* and *ulcers of the cornea*, applied with gentle massage three or four times a day.

Taxus. *Taxus baccata*, L. *Common European Yew Tree.* If *commun*, Fr. *Eibe*, G. (Fam. Coniferae).—The fruit of this handsome evergreen appears to be a deadly poison. In a fatal case the child was found semi-comatose, with convulsions, a cold and clammy skin, difficult respirations, dilated pupils, and making attempts at vomiting. The poison is probably in the seeds. (See 16th edition, *U. S. D.*; also James Thompson, *L. L.*, 1868, 530. For fatal cases in adults, see *M. T. G.*, 1870, ii.; also *L. L.*, 1870, 471; also *P. J.*, 1870, 361.) W. Marmé obtained from yew seeds and leaves an alkaloid, $C_{37}H_{51}NO_{10}$, to which the name of *taxine* has been given. It was a white, poisonous, crystalline powder, only slightly soluble in water, easily soluble in ether, alcohol, chloroform, benzene, and carbon disulphide, but not in petroleum benzin. It fused at $80^{\circ} C.$ ($176^{\circ} F.$). With concentrated sulphuric acid it gave a red color, but dissolved without color in nitric and phosphoric acids. (*A. J. P.*, 1876, 353.) For Vreven's method of isolating taxine, see *P. J.*, 1896, 215. Amato and Capparelli (*Gazz. Chim.*, x, 349) prepared from the leaves a volatile alkaloid, which was soluble in cold sulphuric acid with yellow color, becoming red on heating. They also isolated a nitrogenous crystalline and colorless principle, fusing at from 86° to $87^{\circ} C.$ (186.8° – $188.6^{\circ} F.$), soluble in alcohol, insoluble in water, named *milosin*.

Tayuya.—The root of the *Dermophylla pendulina*, Manso (Fam. Cucurbitaceæ), is used in Brazil, under the name of *tayuya*, in *syphilis*, etc. (*N. E.*, 1877, 234); also, under the same name, the root of the *Trianosperma ficifolia*, Mart. (*Ocypoina maritima*, Cogn.), also of the fam. Cucurbitaceæ (*P. J.*, x, 667), and probably various other roots. In *T. ficifolia* two alkaloids, *trianospermine* and *trianospermitine*, and a bitter principle, *tayuyin*, have been found by Peckoldt (*P. J.*, x, 667), and in *T. dermophylla* a green resin, bitter extractive, and tannic acid were found by the same investigator. (*B. G. T.*, lxxiv., xci. See also *Proc. A. Ph. A.*, xxiv.)

Tea. *Thé*, Fr. *Thee*, G.—The plant which furnishes tea—*Thea chinensis*, L. (*Camellia theifera*, Griff., *C. Thea*, Link.)—is an evergreen shrub belonging to the fam. Ternstræmiaceæ. It is usually from four to eight feet high, though capable, in a favorable situation, of attaining the height of thirty feet. It has numerous alternate branches, furnished with elliptical-oblong or lanceolate, pointed leaves, which are serrate except at the base, smooth on both sides, green, shining, marked with one rib and many transverse veins, and supported alternately upon short footstalks. They are two or three inches long, and from half an inch to an inch in breadth. The flowers are either solitary or supported, two or three together, at the axils of the leaves. They are of considerable size, not unlike those of the myrtle in appearance, consisting of a short green calyx with five or six lobes, of a corolla with from four to nine large unequal snow-white petals, of numerous stamens with yellow anthers and connected at their base, and of a pistil with a three-parted style. The fruit is a three-celled and three-seeded capsule. It has not been certainly determined whether more than one species of the tea plant exists. Linnæus admitted two species—*T. Bohea* and *T. viridis*—differing in the number of their petals; but this ground of distinction is untenable, as the petals are known to vary very much in the same plant. Hayne makes three species—*T. stricta*, *T. Bohea*, and *T. viridis*—which are distinguished severally by the

shape of their leaves and fruit and the direction of the footstalk. De Candolle admits but one species, with two varieties,—the *viridis* or green tea, with “lanceolate flat leaves, three times as long as they are broad,” and the *Bohea*, with “elliptical-oblong, subrugose leaves, twice as long as broad.” Lindley recognizes the two Linnean species, distinguishing them by the leaves, which in *T. viridis* are acuminate, and emarginate at the apex, and in *T. Bohea* are smaller, flatter, darker green, with small serratures, and terminate gradually in a point, but are not at all acuminate or emarginate. (*Flora Medica*, 120.)

The tea plant is a native of China and Japan, and is cultivated in both countries, but most abundantly in the former. In Japan it forms hedge rows around the rice and corn fields; in China, whence immense quantities of tea are exported, whole fields are devoted to its culture. It is propagated from the seeds, which are planted in holes at certain distances, six or eight seeds being placed in each hole, in order to secure the growth of one. In three years the plant yields leaves for collection, and in six attains the height of a man. When from seven to ten years old, it is cut down, in order that the numerous shoots which issue from the stump may afford a larger product of the leaves. These are picked separately by hand. Three harvests, according to Kaempfer, are usually made during the year: the first at the end of February, the second at the beginning of April, and the third in June. As the youngest leaves are the best, the product of the first collection is most valuable, while that of the third, consisting of the oldest leaves, is comparatively little esteemed. Sometimes only one or two harvests are made; but care is always taken to assort the leaves according to their age, and thus originate numerous commercial varieties of tea. The character of the plant, dependent upon the soil, situation, climate, and culture, has also a great influence upon the value of the leaves. It is said that the best tea is procured from the shrubs which grow upon the sides of steep hills with a southern exposure. Though the plant grows both about Peking in the north and Canton in the south of China, it is said to attain greater perfection in the intermediate country, in the neighborhood of Nankin, for instance, where the climate is neither so cold as in the first-mentioned vicinity nor so hot as in the second. Some of the commercial varieties have their origin in this cause, and it is highly probable, though the fact has not been certainly proved, that difference in species may be another source of diversity. After having been gathered, the leaves are dried by artificial heat in shallow iron pans, from which they are removed while still hot, and rolled with the fingers, or in the palm of the hand, so as to be brought into the form in which they are found in commerce. For further particulars as to the cultivation of tea, see *P. J.*, 1871, 386. The odor of the tea leaves themselves is very slight, and it is customary to mix with them the flowers of certain aromatic plants, as those of the orange, different species of jasmine, the rose, *Osmanthus fragrans*, Lour. (*Olea fragrans*, Thunb.), of the Oleaceæ, and *Camellia Sasanqua* (Thunb.), in order to render them pleasant to the smell. The flowers are afterwards separated by sifting or otherwise. (See *P. J.*, xv. 112.) Under the name of *flowers of tea* was at one time sold a waste product consisting of the hair of young leaves, but recently the flowers themselves have

been used to make a beverage (*P. J.*, 71, p. 453). The cultivation of tea has been successfully introduced into Brazil and into the British possessions in India. Samples of Himalaya tea, chemically examined by T. Zoeller, were found to be equal to the best Chinese product, containing at least 5 per cent. of theine and 5.38 per cent. of nitrogen. (*P. J.*, 1871, 162.) Attempts have been made, under the auspices of the government, to introduce tea culture into the United States.

(An elaborate article on tea, with methods of cultivation, etc., by Wm. B. Marshall, U. S. Nat. Museum, will be found in *A. J. P.*, 1903, p. 79.)

Bush Tea and *Honig Thee*, used at Cape Colony, South Africa, as a substitute for tea, are the dried leaves and tops of several species of *Cyclopia*, among which are *C. subternata*, Vog., *C. latifolia*, DC., *C. genistoides*, Vent., and *C. sessiliflora*, Eckl. and Zeyh. (Fam. Leguminosæ). According to the analysis of Henry G. Greenish, they do not contain theine, but a glucosidal body, *cyclopin*, $C_{25}H_{25}O_{13}$. (*P. J.*, xi. 549.)

The gross imports of tea into the United States for the year ending June 30, 1904, amounted to 112,905,541 lbs., valued at \$18,229,310. In 1886, England imported 145,000,000 lbs. of tea from China, and 81,000,000 lbs. from India. Numerous varieties exist in commerce, differing in the shape communicated by rolling, in color, in flavor, or in strength; but they may be all arranged in the two divisions of *green* and *black teas*, which, at least in their extremes, differ so much in properties that it is difficult to conceive that they are derived from the same species.

Under the name of *tea oil* there has appeared in the London markets a Chinese fixed oil said to be derived from *Camellia drupifera*, Lour. (*C. oleifera*, Wall.), a detailed description of which, with tests, may be found in the *P. J.*, vol. xvi. 634. A similar oil is prepared in Japan from the seeds of *Camellia japonica*, L. (*Ibid.*, 837, 764.)

Properties.—*Green tea* is characterized by a dark green color, sometimes inclining more or less to blue or brown. It has a peculiar, refreshing, somewhat aromatic odor, and an astringent, slightly pungent, and agreeably bitterish taste. Its infusion has a pale greenish-yellow color, with the odor and taste of the leaves. According to Warington, who examined numerous varieties of tea carefully, both by the microscope and chemical tests, many of the green teas imported into Great Britain owe their color to a powdery coating, consisting of calcium sulphate and Prussian blue; others to a mixture of these with a yellowish vegetable substance; and others, again, to calcium sulphate alone. (*P. J.*, iv. 37.) *Black tea* is distinguished by a dark brown color. It is usually less firmly rolled and lighter than the green, and contains the petioles of the plant mingled with the leaves. Its odor is fainter, and of a somewhat different character, though still fragrant. Its taste, like that of green tea, is astringent and bitterish, but is less pungent, and to many persons less agreeable. To hot water it imparts a brown color, with its sensible properties of taste and odor. These vary exceedingly in degree in the different varieties, and some black teas are almost wholly destitute of aromatic or agreeable flavor. According to Blyth, green tea is prepared from young leaves which are roasted over a wood fire within an hour or two after being gathered; while the black tea leaves, on the other hand, are allowed to lie in heaps for ten or twelve hours after they have been plucked, during which

time they undergo a sort of fermentation; the leaves then pass through certain processes, and are slowly dried over charcoal fires. (Wynter Blyth, *Foods, Composition and Analysis*, 1903.) A sophisticated tea is largely exported from China, consisting of powdered tea mixed with sand and other earth, and agglutinated with gum; that which is to pass for black being colored with plumbago, and the green with the coating above referred to. On analysis, these teas were found to afford from 35 to 45 per cent. of ashes, while the genuine yields only 5 per cent. A very full account of the adulteration of tea and the methods for the detection of the same may be found in Allen, *Com. Org. Anal.*, 2d edition.

The analyses below¹ by Y. Kozai (*Bulletin No. 7, Imperial College of Agriculture, Japan*) have a special value, owing to the author's knowledge of tea manufacture. Unusual precautions were taken in sampling the leaves, to insure strictly parallel specimens being taken. The figures refer to the moisture-free leaves in each case.

Rochleder found also a peculiar acid, which he calls *boheic acid*, $C_7H_{10}O_6$. According to Stenhouse, the tannin of tea, though always accompanied by a little gallic acid, differs essentially from that of galls; not being, like it, a glucoside, but yielding, under the influence of sulphuric acid, a dark brown substance, almost insoluble in water. (See *A. J. P.*, 1862, 254.) For article on the methods of analysis of tea and a series of analyses of different varieties, see *A. J. P.*, 1887, 626. The volatile oil is citron-yellow, lighter than water, has a strong odor of the tea plant, solidifies easily by cold, and resinifies on exposure to air. It is probably one of the principles upon which depend the effects of tea upon the nervous system. Hence old teas are less energetic than the recently imported; and it is said that the fresh leaves have often produced dangerous effects in China. Nevertheless, the tannic acid is not without influence upon the system; and it is not improbable that the extractive contributes to the peculiar influence of this valuable product. Of these active ingredients, the volatile oil, tannic acid, and extractive are found most largely, according to the analysis of Mulder, in the green tea. *Theine*, $C_8H_{10}N_2O_2$, is a crystallizable principle discovered by Oudry. It was afterwards proved by Jobst to have the same composition as caffeine (trimethyl xanthine). (See *Coffee, Ilex, Kola Nuts, and Guarana*, page 605.) According to Mulder, it exists in tea combined with tannic acid. Theine has a feebly bitter taste; is, in the state of crystals, soluble in 46 parts of water, 53 of alcohol, and slightly soluble in ether; melts at about $236.8^\circ C$. ($458.3^\circ F.$), and at $178^\circ C$. ($352.4^\circ F.$) sublimes in white vapors, which condense in minute needles. From its aqueous solution the following reagents precipitate it; phospho-molybdic acid, yellow pre-

cipitate; iodine with potassium iodide, dirty brown precipitate; platinum chloride, yellow hair-like crystals insoluble in cold hydrochloric acid, slowly separating; auric and mercuric chlorides and silver nitrate also give precipitates. Infusion of galls causes a deposit of theine tannate, which is again, however, dissolved by heating the water. Kossel discovered in 1888 a related principle, *theophylline* (*dimethylxanthine*), but only in very small amounts. It is now made synthetically and has been introduced into medicine. (See *Theoicine*).

The proportion of theine found in tea varies considerably, the general range being from three to four per cent. India and Ceylon tea usually contain slightly more than four per cent.

Tea is astringent and gently excitant, and exerts a decided influence over the nervous system, evinced by the feelings of comfort and even exhilaration which it produces, and the unnatural wakefulness to which it gives rise when taken in unusual quantities or by those unaccustomed to its use. It is almost exclusively used as a beverage. Taken moderately, and by healthy individuals, it may be considered as perfectly harmless; but long continued in excessive quantity it is capable of inducing unpleasant nervous and dyspeptic symptoms. Green tea is decidedly more injurious in these respects than black, and should be avoided by dyspeptic individuals, and by those whose nervous systems are peculiarly excitable. As a medicine, tea may sometimes be given advantageously in *diarrhæa*, and a strong infusion will often be found to relieve *nervous headache*. An extract is made from it in China which is said to be useful in fevers. (See *Fluideextractum Camellie*, National Formulary.)

Tegmin.—Under this name a surgical dressing has been recommended; it is an emulsion made from yellow wax, one part; acacia, two parts; water, three parts; it also contains 5 per cent. of zinc oxide and a little wool fat. It is used as a protective and vehicle for skin remedies.

Telfairia Pedata, Hook. (*Joliffa africana*, Delile.)—The seeds of this East African plant yield a deep yellow fragrant oil, of specific gravity 0.918, containing *telfairic acid*. (*Chem. Zeit. K.*, xxiv. 24.)

Tellurium. (Te. Atomic weight, 126.6.)—The first physiological investigations as to the action of tellurium were made by Hansen (*Chem. Gaz.*, 1854), who found that the *potassium tellurate* produces in dogs vomiting, with stupor, and that in the dose of one grain three times a day it causes in man cardiac oppression, nausea, some salivation, with a pronounced garlic-like odor of the breath. These investigations have been extended and confirmed by William J. Gies (*M. A.*, June, 1901), who found that in doses of one-third of a grain per kilogramme sodium tellurate caused in the dog vomiting, diarrhæa, uncon-

¹ Analyses of Tea (percentage composition).

	Unprepared Leaves.	Green Tea.	Black Tea.
Caffeine or Theine	3.30	3.20	3.30

sciousness, paralysis, convulsions, and death, with pronounced inflammatory changes in the intestines and kidneys similar to those seen after arsenic. Characteristic was the pigmentation of all parts of the body by metallic tellurium. During life the brown or greenish discoloration of urine and the very pronounced garlicky odor of the breath were almost diagnostic. The continuous administration of minute doses had no effect upon metabolism, but if the amount ingested was increased, gastro-intestinal irritation with restlessness soon appeared. Tellurium was found in the feces, urine, breath, and skin secretions. In man drowsiness, nausea, and constipation seemed to result from the remedy, given in doses up to half a grain. There was also a marked anhidrotic action, even in healthy men, appearing fifteen minutes to one hour after the ingestion of the dose. Potassium tellurate is an efficient remedy for the arrest of *colliquative sweating*, but the pronounced alliaceous odor which it imparts to the breath, and even to the perspiration, greatly interferes with its use. Dose of potassium or sodium tellurate, one-sixth to one-half of a grain (0.01–0.032 Gm.).

Tephrosia. *Cracca virginiana*, L. (*T. virginiana*, Pers.) Turkey Pea. Wild Pea. Catgut. Goat's Rue. Hoary Pea. Devil's Shoestring. *Tephrosia*, Fr., G. (Fam. Leguminosæ.)—Several species of *Cracca* are employed in different parts of the world, though unknown in general commerce. They are leguminous plants, shrubby or herbaceous, with leaves unequally pinnate, and flowers in axillary or terminal racemes. They are generally possessed of cathartic properties, their leaves or roots being employed. Plugge (*Proc. A. Ph. A.*, 1897, 560) examined the root of *T. macropoda* and found a poisonous active principle, not identical with cytisine. *Cracca virginiana*, L., grows in most parts of the Eastern United States. It is a foot or two high, with pubescent stems and leaves and handsome terminal flowers. (See Griffith's *Med. Bot.*, 237.) The roots, which are slender, long, and matted, are tonic and aperient, and are said to have been used by the Indians as a vermifuge, given in the form of decoction.

Terpinol.—This is not a simple body, but a mixture of terpenes with variable proportions of an alcohol, *terpineol*, $C_{10}H_{17}OH$. It forms a colorless oily substance with a hyacinthine odor; it is produced by boiling terpin with diluted mineral acids. It is insoluble in water, but readily soluble in alcohol and ether. Terpinol has been used in chronic bronchial catarrh, and is especially commended by Lazarus when there is much irritation of the membrane with scanty secretion. Janowsky states that it is a valuable remedy in hæmoptysis. The dose is three to five minims (0.2–0.3 Cc.) at intervals of from one to four hours, administered in capsules.

Terraline. *Terroline*.—A liquid proprietary petroleum product, odorless and tasteless, used internally in emulsions, in the dose of from one to two fluidrachms (3.75–7.5 Cc.). See *Petroleum Liquidum*, page 924.

Testa Præparata. Prepared Oyster-shell. *Magistère de Coquilles (d'écailles) d'Huitres*, Fr. *Præparirte Austerschalen*, G.—“Take of Oyster-shell a convenient quantity. Free the Oyster-shell from extraneous matter, wash it with boiling water, and, having reduced it to a fine powder, treat this in the manner directed for Prepared Chalk.” U. S. 1870. Prepared oyster-shell differs

from prepared chalk in containing animal matter, which, being very intimately blended with calcium carbonate, is supposed by some physicians to render the preparation more acceptable to a delicate stomach. It is given as an antacid in *diarrhæa*, in the dose of from ten to forty grains (0.65–2.6 Gm.) or more, frequently repeated. A preparation was introduced into use in this country, under the name of *Castillon's powders*, consisting of sago, salep, and tragacanth, each, in powder, a drachm, prepared oyster-shell a scruple, and sufficient cochineal to give color to the mixture. A drachm of this is boiled in a pint of milk, and the decoction used *ad libitum* as a diet in chronic bowel affections.

Tetragastris. *Tetragastris panamensis* (Engl.). *Hedvigia balsamifera* (Engl.). *Bois Cochon*, or *Sucrier de Montagne*, Fr. (Fam. Burseraceæ.) This native of the Antilles has been examined by Gaucher, Combemale, and Marestang (*France Méd.*, October, 1888), who find in it an alkaloid and a resin. The extract of the root and stems produces in the guinea pig rapid and considerable lowering of temperature, progressive paralysis, general convulsions, dilatation of the pupils, respiratory irregularity, and cardiac paresis. The alkaloid was found to be a convulsive agent, acting upon the spinal cord. The resin, which seemed much more active than the alkaloid, acted as a paralyzant.

Tetranthera.—From the bark of the lauraceous plant, *T. citrata* (T. *Brava*, Bl., *T. intermedia*, Bl.), J. D. Filippo has extracted an alkaloid, *lauro-tetanine*. (See *A. Pharm.*, 1898, 601.)

Teucrium. *Teucrium Chamædrys*, L. *German-der*. *Chamædrys*. *Petit Chêne*, Fr. *Edlar*, *Gaman-derlein*, *Frauenbiss*, G.—A small European labiate, which has been employed as a mild corroborant in uterine, rheumatic, gouty, and scrofulous affections, and intermittent fevers. Germander was an ingredient in the *Portland powder*, noted as a remedy in gout. This powder, according to the original prescription, consisted of equal parts of the roots of *Aristolochia rotunda*, L., and *Gentiana lutea*, L., of the tops and leaves of *Teucrium Chamædrys*, L., and *Erythræa Centaurium* (L.), Pers., and of the leaves of *Ajuga Chamæpitys*, Schreb., or ground pine. The dose was a drachm every morning before breakfast for three months, then forty grains for three months, afterwards half a drachm for six months, and finally half a drachm every other day for a year. (Parr.) Two other species of *Teucrium* have been used in medicine,—*T. Marum*, L., *cat thyme*, or *Syrian herb mastich*, indigenous in the south of Europe, and *T. Scordium*, L., or *water germander*, growing in the higher latitudes of the same continent. The former is a warm, stimulating, aromatic bitter, and has been recommended in *hystéria*, *amenorrhœa*, and *nervous debility*; the latter has the odor of garlic, and a bitter, somewhat pungent taste, and was formerly highly esteemed as a corroborant in *low forms of disease*; but neither of them is now much employed. *T. Marum* is an errhine, and was formerly an ingredient of the *Pulvis Asari Compositus*. The dose of either of the three species is about half a drachm (2.0 Gm.). A plant said to have been used advantageously in *cholera* in the Levant, a specimen of which was sent to Paris, proved to be *Teucrium Polium*, L. (*J. P. C.*, xv. 352.) Moorhof (*Ph. Cent.*, 1893, 89) prepared a purified liquid extract from *T. Scordium*, and named it *teucriin*, which he recommends in the treatment of fungoid diseases and abscesses.

Tfol is an argillaceous earth, containing free gelatinous silica, which is largely used in Northern Africa as a substitute for soap. It has been strongly recommended by Lahache for the purpose of emulsifying tar oil and for disinfecting purposes.

Thalictrum.—It appears probable that many species of this genus (Fam. Ranunculaceæ) have active medicinal or toxic properties. In 1879 Henriot and Doassans asserted that they had separated from the roots of the *Thalictrum macrocarpum*, Gren., a crystalline yellow substance, having very pronounced toxic principles, analogous to those of curare; and subsequently stated (C. R. S. B., 1880) that this substance really consists of two principles,—an alkaloid, *thalictrine*, obtained in the form of prismatic needles, insoluble in water, soluble in alcohol, forming crystalline salts with acids, and *macrocarpin*, a yellow crystalline body, soluble in water, representing the coloring principle of thalictrum. Subsequently *berberine* was found by Doassans and Mousset in *Thalictrum flavum*, L., *Fen Rue* or *Monk's Rhubarb*, *macrocarpin* being, according to this authority, very closely allied to *berberine*, but differing in that its color is not affected by ammonia. Rochebrune (*Toxicolog. Africaine*, i.) has found both thalictrine and *macrocarpin* in the roots of *Thalictrum glaucum*, Desf., of Spain. Thalictrine he states to be a very active cardiac poison, producing loss of power, convulsive movements, irregularity and depression of the heart's beat, and finally death in some cases in convulsions. According to Rochebrune, thalictrine also exists in the African species *Thalictrum rhyncho-carpum*, Q. Dillon and A. Rich.

Thalline. *Tetrahydroparaquinianisol* or *Tetrahydroparamethyloxyquinoline*. $C_9H_8H_4N(OCH_3)$. The term *anisol* is applied to the methyl ether of phenol, and it is therefore methyloxybenzene. Skraup's synthesis of quinoline, C_9H_7N , was effected by heating aniline or amidobenzene with nitrobenzene, glycerin, and sulphuric acid. By taking instead paramidoanisol, paranitroanisol, glycerin, and sulphuric acid, Skraup obtained paraquinianisol, $C_9H_8N(OCH_3)$. This is then treated with tin and hydrochloric acid, when it takes up four atoms of hydrogen and becomes $C_9H_8H_4N(OCH_3)$. The name thalline was given to this base because of the deep green color produced by ferric chloride and other oxidizing agents. The base thalline is obtained in well-formed rhombic crystals, which fuse at $40^\circ C.$ ($104^\circ F.$), and recrystallize on cooling. It shows a neutral reaction and has a characteristic aromatic odor resembling that of coumarin. It is soluble in water, alcohol, and ether.

Thalline sulphate is a white crystalline powder which loses its two molecules of water of crystallization at $100^\circ C.$ ($212^\circ F.$) and melts at $110^\circ C.$ ($230^\circ F.$). It is soluble in five times its weight of cold water and freely soluble in boiling water, soluble in 100 parts of alcohol. Both solutions turn brownish on exposure to air and light. The odor of the sulphate recalls that of anisol. **Thalline tartrate** is a white crystalline powder, fusing at $155^\circ C.$ ($311^\circ F.$), and possessing a coumarin-like odor. It is soluble in ten parts of water and hardly soluble in alcohol. Its aqueous solution has an acid reaction.

Thalline tartrate and sulphate are medicinally equivalent. They are powerful antipyretics, acting also, when in sufficient dose, as depressants both upon the vasomotor system and upon the

heart, and, according to A. Robin, checking tissue waste in the body, and having a very marked tendency to attack the red blood corpuscles. These salts have been used in practical medicine, in doses of from four to eight grains (0.26–0.5 Gm.), but are so prone to produce disagreeable symptoms, such as marked cyanosis, vomiting, diarrhœa, albuminuria, etc., that their employment has been abandoned. According to Kreis, in from 4 to $4\frac{1}{2}$ per cent. solution they are active germicides, and the frequent use of urethral injections of the 1 to 2 per cent. solution has been found very useful in *chronic gonorrhœa*. Moncorvo states that thalline is an active hæmostatic.

Thallium. (Tl. Atomic weight, 202.6.)—This metal, discovered by spectrum analysis, has been found to prevail widely in nature. The credit of its discovery by Crookes in 1861 has been disputed by Lamy. Although the absorption of the salts of thallium appears to be slow they are certainly distributed everywhere, their presence having been recognized by Lamy by the green spectroscopic line in all the tissues of poisoned animals. Small doses may be tolerated for a short time, but according to William Marmé have a cumulative effect, so that after the continued use of the poison the appetite is impaired, intestinal pain is felt, and vomiting occurs, with diarrhœa, hemorrhage, salivation, and emaciation. General debility, embarrassed respiration, weakness of the circulation, disordered muscular action, as tremors and want of co-ordination are added to the other symptoms, and, when the poisoning becomes general, conjunctivitis, with free secretion of mucus, is a frequent symptom. After death, small effusions of blood and infiltration of the lungs are observed, as are also intense congestion of the bowels, copious pericardial effusion, and ecchymoses on the heart's surface. Cases of poisoning in man have been extremely few, but in a physician who took for experimental purposes from two to four grains (0.13–0.26 Gm.) in a week, and a month later the same amount in similar manner, no symptoms followed the first lot taken except numbness of the toes and finger tips. The second dose produced diarrhœa, increased numbness of the feet and hands, extending to the body, with pains, muscular weakness, and tenderness over the nerve trunks, especially in the lower extremities. As both lead and arsenic, however, were found in the urine of this patient, some doubt must exist how far the symptoms were really due to thallium. (Ballard, *Reports Boston City Hospital*, 1902.) That thallium, however, can produce widespread general neuritis is strongly indicated by the violent pains, especially of the legs, which have been noted by Lamy, by Combemale, and other observers, and also by the muscular atrophy which appears to be pronounced in chronic poisoning by the drug in the lower animals. Curci indeed claims that thallium is exclusively a muscle poison, and as long ago as 1874 Rabuteau recorded that after death from thallium the muscles did not respond to irritation. (See *Ed. M. J.*, 1874.)

A symptom which was produced in the lower animals by Buschke and by Bettmann, and has been reported in various cases as occurring in man, is loss of hair. Thus, Guinard, in 1898, found that the taking of nine pills of 0.05 Gm. each of the thallium acetate was followed by pronounced alopecia. Pozzi and Courtade assert that in some cases thallium causes swelling of the gums with a blue line at the junction with the teeth, but

this symptom seems not to have been noticed by other observers. In 1898 Combemale claimed that in doses of one and a half grains (0.096 Gm.), given at bedtime, thallium acetate is a valuable remedy in the *colliquative sweats* of phthisis; that it is effective has been proved by Huchard and others; but in many cases it has produced severe peripheral pains, loss of hair, abdominal disturbance, and other very disagreeable symptoms.

Thanatol. *Guæthol. Ajacol. Pyro-catechin-mono-ethyl-ether.* $C_8H_4<\begin{smallmatrix} OC_2H_5(1) \\ OH(2) \end{smallmatrix}$ This is an oily liquid, homologous with guaiacol, and having similar medicinal properties. See page 1507.

Thapsia. *T. Garganica, L. Thapsie, Fawo Fenouil, Fr. Thapsie, G.*—An umbelliferous plant, growing in Southeastern Europe, and well known to the ancients, named from the isle of Thapsos, where it was obtained. Theophrastus speaks of its root as emetic and purgative. After long neglect this plant has obtained a foothold in the French Codex, which recognizes a *Resina Thapsie* prepared by exhausting the bark of the root with alcohol and evaporating to a soft extract. From this extract the Codex further directs that an *Emplastrum Thapsie* shall be so prepared as to contain 7 per cent. of the resin combined with yellow wax, turpentine, and colophony. The bark of the root and the resin are both objects of commerce. The bark is described by Stanislaus Martin as almost always doubly quilled, unless where altogether in small fragments, exteriorly rugose with the epidermis here and there detached in patches larger or smaller, and of a deep brown color, interiorly smooth and whitish, and of a fibrous fracture. The size of the pieces varies, the largest not exceeding twenty-four inches in length and an inch in circumference. At the point where the root is attached to the stem there is often adherent a ligneous fibre about an inch long, and over the whole surface there are found but few radicles. It is said that great care is necessary, in removing the root from the bales, not to be injured by the powder which escapes, and which causes itching and swellings of the face and hands. By submitting thapsia to the successive action of alcohol and ether Pressoir obtained two resins. Sulphuric acid colored that soluble in alcohol scarlet, that soluble in ether blue. (*J. P. C.*, 4e sér., xi. 328.) Canzoneri finds that the ethereal extract is an amber-colored syrupy resin possessing vesicating properties. From it he has obtained two acids, *octoic* or *caprylic* acid, and *thapsic* acid, besides a neutral non-nitrogenous vesicating substance. (See *A. J. P.*, vol. xiv. 325.) Cazenave objects to the plaster prepared from the resin, and kept in masses, as it deteriorates by time. He proposes the following method of preparing a plaster extemporaneously when wanted. Dissolve the resin in alcohol, and with the aid of a brush spread it on a suitable recipient, which may be ordinary plaster, waxed taffetas, or simply gummed paper. A single layer is sufficient for the purpose of an active revulsion, but the effect may be increased at pleasure by increasing the number of layers. (*J. P. C.*, 1868, 29.) The French thapsia plaster is an exceedingly active counter-irritant, producing much inflammation of the skin with an eczematous eruption and intolerable itching, and, if the application be maintained, finally an ulcerated and suppurated surface, which on healing

leaves behind it pronounced scars. The therapeutic action of the plaster is that of a severe counter-irritant.

The resin from the root of *Thapsia Sylphium*, St.-Laz., an Algerian plant, which most botanists believe to be a simple variety of *T. Garganica*, L., is, according to Herlaut, more active than that of the official plant. (*Proc. A. Ph. A.*, xxvi. 250.) Heckel and Schlagdenhauffen (*N. R.*, June and July, 1887) find in the root of *Thapsia villosa*, L., a vesicant resin, which acts more slowly and gently than does that of *T. Garganica*.

Theobromine-acetyl-methylene-salicylate. *Diurazin.*—This is said to be a condensation product containing 30 per cent. of theobromine, 55 per cent. of salicylic acid, and 6 per cent. of formaldehyde, and has been recommended as a diuretic in dropsy in doses of six grains (0.4 Gm.).

Thermin. *Tetrahydro-β-naphthylamine Hydrochloride.* $C_{10}H_7H_4NH_2.HCl$.—The tetrahydro addition compound is formed when metallic sodium is caused to act upon naphthylamine in boiling amyl alcohol solution. The hydrochloride has been brought forward by Filehne of Breslau, as a local mydriatic of extraordinary power. It is asserted that in from 1 to 5 per cent. solution it dilates the pupil more widely than does atropine.

Thermodin. *Acetyl para-ethoxy-phenyl-urethane.* $C_8H_4(OC_2H_5)N(COCH_3)COOC_2H_5$.—A derivative of urethane in the form of a colorless, crystalline powder, fusing at from 86° to 88° C. (186.8°–190.4° F.), insoluble in water. It is used as an antipyretic in doses of from five to fifteen grains (0.32–1.0 Gm.).

Thermol. *Acetyl-salicyl-phenetidin.* $C_{17}H_{17}NO_4$.—This substance, proposed by S. Lewis Summers, is a white, crystalline, odorless, tasteless powder, which is claimed to be a harmless and active antipyretic and analgesic, and as such has been used to a considerable extent in typhoid fever, neuralgia, dysmenorrhœa, migraine, etc.; also, as an antispasmodic in whooping cough. Dose, three to fifteen grains (0.2–1.0 Gm.).

Thevetia. *Yccotli.*—Inhabiting the damp, hot valleys of the Mexican Cordilleras is a large tree belonging to the Apocynaceæ, whose fruits are known by the natives as *huesos ó codos de fraile*, or *friar's elbow bones*, and are used as a topical application in hemorrhoids. The tree is the *Thevetia Yccotli*, DC. (*A. DeC.*, *Prodromus*, viii. 343.) In the seeds Herrera found a glucoside, *thevetin*. (*A. J. P.*, 1877, 145.) Closely allied to *T. Yccotli* is *T. nereifolia*, Juss. (*Prodromus*, viii. 343), a tree which probably grows also in Mexico, but has been found by botanists chiefly, if not solely, in the West Indian Islands, Colombia, Peru, and others parts of South America. De Vrij very many years ago discovered in its seeds a glucoside which was closely studied by Blas. (*Neues Jahrb. f. Pharmacie*, Bd. xxxiv. 1854, 1.) He gave it the name of *thevetin*, and the formula $C_{52}H_{84}O_{24}$, and believed it to be identical with *cerberin*, previously found by Oudemann in *Cerbera Odallam*, Ham., also an apocynaceous plant. Plugge (*A. Pharm.*, 1893, 10) has made a very thorough study of the *cerberin* from *Cerbera Odallam*, Gaertner, and finds that it is not identical with either tanghinin or thevetin. With the former it is isomeric, showing the same percentage composition, but has different crystalline form and melting point,—*cerberin* 192° C. (377.6° F.), *tanghinin* 182° C. (359.6° F.). From *thevetin* it

differs not only in composition, but in the nature of the decomposition products. Cerberin, $C_{27}H_{40}O_8$, is decomposed into *cerberetin*, $C_{19}H_{26}O_4$, a citron-yellow amorphous powder melting at 85.5° C. (186° F.), and glucose, while thevetin, $C_{54}H_{84}O_{24}$, is split into *theveresin*, $C_{48}H_{70}O_{17}$, a white powder, and glucose.

Merck (*Jahresh. für* 1892, 57) has described a glucoside *cerberin* to which he gives the formula $C_{25}H_{38}O_{12}$. He states that it was obtained from a Mexican plant, probably *Thevetia Yccotli*. Whether this glucoside is identical with the thevetin of Blas cannot be definitely stated. Blas found that the thevetin of De Vrij boiled in diluted sulphuric acid splits into glucose and *theveresin*, which has the formula $C_{48}H_{70}O_{17}$. Thevetin occurs in minute crystals, odorless, of bitter taste, slightly soluble in cold water (twelve parts), freely so in boiling water, diluted and strong alcohol, acetic acid, insoluble in ether. Its most characteristic reaction appears to be its dissolving in concentrated sulphuric acid, with the production of a reddish-brown color, changing to a cherry-red, and after some hours to a violet color. In commerce it occurs as a yellowish-white, amorphous bitter powder, easily soluble in water and alcohol. Theveresin is only slightly soluble in boiling water. These substances are active poisons. A number of cases of poisoning by the seeds of the East Indian thevetia have occurred; the symptoms have been repeated vomiting, a slow, very feeble pulse, delirium, convulsive movements, and coma. The physiological action of the thevetin from *T. nereifolia* has been investigated chiefly by König. (*A. E. P. P.*, Bd. v. 228.)

David Cerna finds that the glucoside of *T. Yccotli* (*P. M. T.*, ix. 396) with sulphuric acid affords a clear greenish-yellow solution gradually passing to brown and brownish violet, and finally becoming a permanent cherry-brown color, which changes on the addition of potassium bicarbonate to an emerald-green; also that it is in moderate doses stimulant both to the circulation and respiration, but finally paralyzes the heart muscle and the respiratory apparatus; that it causes cerebral convulsions and spinal paralysis, abolishing sensation and reflex activity before voluntary movement by an influence upon the sensory nerves or spinal tract. Zotos N. Zotos (*In. Dis.*, Dorpat, 1892) states that *cerberin* belongs physiologically to the digitalin group.

Thialdine. $C_6H_{13}NS_2$.—This substance, obtained when hydrogen sulphide acts upon aldehyde-ammonia in aqueous solution, forms crystals melting at 43° C. (109.4° F.), which are but slightly soluble in water, more easily in alcohol. It has been investigated by Lusini, who found it a general paralyzing agent, acting powerfully upon the heart, which it arrests in diastole; while *carbothialdine*, $C_5H_{10}N_2S_2$, formed by the action of carbon disulphide in alcoholic solution upon aldehyde-ammonia, acts as a tetanizing agent and does not affect the heart. (*See Nowv. Rem.*, Nov. 1890.)

Thigenol.—This proposed substitute for ichthyl is said to be the sodium salt of a sulphonic acid of a synthetic sulphur oil, and has been used in 20 per cent. ointment for the treatment of *dermatitis*, *prurigo*, and other diseases of the skin. (*K. T. W.*, 1902, No. 6.)

Thilanin.—This substance is said to be made by the action of sulphur upon lanolin. It is of the consistence of lanolin, of a brownish color

and peculiar odor. It is said not to be irritating, and has been used without dilution with asserted excellent results in *chronic eczema* and other *skin eruptions* in which uncombined sulphur has been employed.

Thiocol. Potassium Guaiacol Sulphonate.
 $C_6H_5 \begin{cases} OH \\ OCH_3 \\ SO_3K \end{cases}$ This is a fine white powder, having

a taste at first bitter and afterwards sweetish; readily soluble in water; containing about 60 per cent. of guaiacol. It is pleasant to the taste and not irritant to the gastric or other mucous membranes. Its freedom from odor, ready absorption and non-irritant action on the mucous membrane are among its recommendations that have been reported by its introducers. The original commendation of it by C. Schwartz (*K. T. W.*, 1898), in *tuberculosis*, *chronic bronchitis* and *intestinal catarrh*, has been confirmed by various clinicians. Forty-five grains (3.0 Gm.) of it may be given during the day, increased to one hundred grains (6.5 Gm.) a day.

Thiol.—This is a thin, dark brown, neutral liquid, with an odor somewhat like that of Russia leather, having a specific gravity of from 1.082 to 1.089; its aqueous solution is transparent, froths when shaken, and is not precipitated by strong alcohol; it is also feebly soluble in glycerin. On evaporation, liquid thiol yields about 40 per cent. of dried thiol. It is prepared from paraffin oils of from 0.89 to 0.90 sp. gr., which are treated with sulphur at high temperatures. The unsaturated hydrocarbons (olefins, etc.) are alone attacked, and these are then extracted by suitable solvents from the saturated hydrocarbons. They are then acted upon by concentrated sulphuric acid at low temperatures, and the thiol separated out by the addition of ice. It may then be evaporated *in vacuo* to either *thiolium liquidum* or *thiolium siccum*. It is asserted that thiol possesses the remedial properties of ichthyl, and is superior on account of being odorless. It has been used in *eczema*, *syphilitic* and other *superficial ulcerations*, *acute infiltration of joints*, *sprains*, *contusions*, *erysipelas*, etc., precisely as has ichthyl. The liquid is used in the form of a solution or ointment; the dried thiol is sometimes employed as a powder. In *rheumatism* thiol has been given internally in doses of from five to ten minims (0.3–0.6 Cc.), or the dried preparation in doses of from one to two grains (0.065–0.13 Gm.).

Thiolic Acid.—This is a darkish green extract-like mass, having the odor of mustard, which has been called *sulphurated linseed oil*. It is insoluble in water; soluble in alcohol. Its alkaline combinations, especially with the sodium salts, have been recommended as substitutes for thiol and ichthyl.

Thiophene (C_4H_4S) was recognized by Victor Meyer in 1883 as being an invariable accompaniment of benzene as produced from coal tar, and because of the similarity of properties adhering very closely to it through all reactions. It can be separated by shaking up the benzene with one-tenth of its bulk of concentrated sulphuric acid until the addition of a little isatine no longer produces a blue color (indophenin reaction). Thiophene is a colorless, mobile oil, of faint odor, and boils at 84° C. (183.2° F.). Just as benzene is accompanied in coal tar by toluene, xylene, and higher homologues, so thiophene is accompanied by *thiotolene* (*methyl-thio-*

phene), $C_6H_5S.CH_3$, and *thiovene* (dimethyl-thiophene), $C_6H_5S.(CH_3)_2$. Thiophene and its homologues yield a large number of brilliant dye colors analogous to those derived from benzene. It was first physiologically tested by A. Heffter (A. G. P., 39, 420), who found that it appeared in the urine, and lessened the elimination of sulphuric acid in the urine. E. Spiegler (Th. M., Feb. 1892) has employed in skin diseases—1, Sodium thiophene sulphonate, $C_6H_5S-NaSO_3$; 2, Thiophenediiodide, $C_6H_4I_2S$. The first of these compounds is a white crystalline powder, containing 33 per cent. of sulphur, having a feeble, disagreeable odor. It was found in the form of an ointment to act very well in *prurigo* with *eczema*. Thiophenediiodide occurs in tabular crystals, melting at $40.5^\circ C.$ ($105^\circ F.$), having a characteristic, not disagreeable odor, insoluble in water, but very feebly soluble in ether, chloroform, and warm alcohol, soluble with difficulty in cold alcohol; containing 75.5 per cent. of iodine and 9.5 per cent. of sulphur. It was found to be antiseptic and is one of the compounds suggested as a substitute for iodoform.

Thioresorcin. $C_6H_4(OS)_2$.—A yellowish-gray powder, insoluble in water, made by fusing together one molecule of resorcinol and two molecules of sulphur. It has been recommended as a substitute for iodoform, but has given rise to unpleasant symptoms.

Thiosapol.—Soap containing from 5 to 10 per cent. of sulphur in combination, used in treating skin diseases.

Thiosinamin. *Allyl-sulpho-urea*. *Allylsulphocarbamide*. $CS \begin{Bmatrix} NH_2 \\ NH(C_6H_5) \end{Bmatrix}$. This occurs in colorless monoclinic or rhombic crystals, of a bitter taste and feeble garlic-like odor. It is moderately soluble in water, very soluble in alcohol and ether. It possesses no bactericidal properties, and in the doses in which it has been used seems to exert no influence whatever upon the general system, except upon the blood making organs. Several hours after its injection the leucocytes in the blood are greatly diminished in number, falling, according to Hebra, in some cases from 14,000 to 4000. This condition lasts, however, but a short time, and is followed by a pronounced hyperleucocytosis. During the latter period a very pronounced destruction and absorption of exudates and of cicatricial and other poorly nourished tissues occur.

It was introduced originally into medicine by Von Hebra (*Internat. klin. Rundschau*, Sept. 1892) in the treatment of lupus and old cicatrices, and has been used by many clinicians in the treatment of *lupus*, *chronic glandular inflammations*, *keloid*, *urethral strictures*, *corneal opacities* and *sclerotic conditions of the ear* with consequent deafness. Unna has also employed it locally in the form of the 5 to 20 per cent. soap or plaster in *fibrous tumors*, *keloid*, *leprosy*, and *syphilitic lesions*, and in *smallpox scars*. Its local application may be continued for some hours and is said not to produce irritation or pain. It has been given by the mouth in capsules in doses of one-half to three grains (0.032–0.2 Gm.), or hypodermically in one to four grains (0.065–0.26 Gm.), in a 10 to 15 per cent. alcoholic solution preferably administered in the intrascapular or gluteal region. Considerable pain is produced by the injection. In superficial diseases injections may well be made in the neighborhood of the lesion. According to K.

Lange, thiosinamin is toxic in overdose. Hebra used the 15 per cent. alcoholic solution injected into the back in such quantity that the patient receives from four and one-half to seven grains (0.32–0.45 Gm.) of the thiosinamin, repeating the injection every third or fourth day. A solution may be made by dissolving 10 parts in 100 parts of a sterile mixture of water and glycerin, which keeps well and is non-irritant. As a full dose, twelve or fifteen minims (0.7–0.9 Cc.) of this solution may be injected into a muscle every third day.

Thiuret. $C_6H_7N_3S_2$.—A sulphurated compound made by the oxidation of *phenyl-dithiobiuret*; it is a bulky, inodorous, crystalline powder, insoluble in water, soluble in alcohol and ether, easily decomposed by alkaline solutions with liberation of sulphur. It is used as a substitute for iodoform.

Thuja. U. S. 1880. *Arbor Vitæ*.—*Thuja occidentalis*, L. (Fam. Conifere), is specifically characterized by the peculiarities of the leaves, the pointless cone-scales, and the broad wings extending all around the seeds. It attains a height of fifty feet and a diameter of three feet, but is usually much smaller, and grows in swampy grounds from Pennsylvania northward and westward, often forming extensive "cedar swamps." In Canada and the extreme northern parts of the United States it is commonly called *white cedar*, a name sometimes applied to *Chamaecyparis thyoides* (L.), B. S. P. (*Cupressus thyoides*, L.), which latter is more properly called *Southern white cedar*. The wood is reddish, soft, fine-grained, and very durable. The leaves, or small twigs invested with the leaves, are the parts used. They have an agreeable balsamic odor, especially when rubbed, and a strong, balsamic, camphoraceous, bitter taste, and are flattish, two-edged, with the scale-like leaves appressed and closely imbricate in four rows, rhombic-ovate, obtusely pointed, with a roundish gland upon the back. A Kewalier of Vienna, found in them volatile oil, a bitter principle called *pinipicrin*, $C_{22}H_{34}O_{11}$, found also in *Pinus sylvestris*, sugar, gelatinous matter, a variety of wax, resin, and tannic acid; also a peculiar crystallizable coloring principle, *thujin*, to which he gives the formula $C_{20}H_{22}O_{12}$. It is of a citron-yellow color and an astringent taste, soluble in alcohol, inflammable, and when its alcoholic solution is heated with diluted hydrochloric or sulphuric acid it splits up into glucose and *thujigenin*,

and by continuing the reaction another molecule of water is taken up by the latter and *thujetin*, $C_{14}H_{14}O_8$, is formed. Thujetin is possibly identical with quercetin. When thujin is heated with barium hydroxide, instead of thujetin is obtained another product, *thujetic acid*, $C_{28}H_{22}O_{18}$. The same chemist determined that the tannic acid of this plant is identical with *pinitanic acid*, which he had previously obtained from the leaves of *Pinus sylvestris*, L. (See, for details, *Chem. Gaz.*, Nos. 392, 393, 1859.) According to Hübschmann, the leaves and twigs of *Thuja occidentalis* yield also 1 per cent. of an essential oil of sharp, camphor-like taste, sp. gr. 0.925, boiling point from 190° to $206^\circ C.$ (374° – $402.8^\circ F.$), and easily soluble in alcohol. According to *Schim. Rep.*, April, 1897, thuja oil contains *pinene*, *fenchone*, *thujone*, and probably *carvone*.

Oil of White Cedar.—F. K. Bailey reports the case of a girl, aged fifteen, who took sixteen drops of the oil of white cedar, and directly after-

wards fell unconscious, with clonic spasms followed by epileptiform convulsions lasting at intervals for several hours. Long-continued irritation of the stomach resulted. (*N. R.*, 1872.)

In the form of decoction, thuja has been used in *intermittent fever*, and, according to Schoepf, in *coughs, fevers, scurvy, and rheumatism*, and as an emmenagogue. Made into an ointment with lard or other animal fat, the leaves are said to form a useful local application in rheumatic complaints. A yellowish-green volatile oil, which may be obtained from the leaves by distillation, has been used with success in *worms*. According to Hildebrand both *fenchone* and *thujone* act as stimulants to the heart muscle (*A. E. P. P.*, Bd. 48). The dose of the fluidextract is a fluidrachm (3.75 Cc.) from three to six times a day.

Thymacetin. $C_8H_2(CH_3)C_3H_7 \begin{cases} OC_2H_5 \\ NH(C_2H_5O) \end{cases}$.

This is a white crystalline powder, slightly soluble in water, having the same chemical relation to thymol that phenacetin has to phenol. It should show, therefore, the general characters of phenacetin with the antiseptic character of thymol. According to Jolly (*Cb. G. T.*, Feb. 1892), it is a very valuable analgesic and hypnotic. *Dose*, from three to fifteen grains (0.2–1.0 Gm.), best given in capsules.

Thymoform. $2[C_6H_3(CH_3)(C_2H_7O)] \cdot CH_3$.—It is made by heating 100 parts of thymol with 100 parts of a 40 per cent. solution of formaldehyde and gradually stirring in 100 parts of concentrated hydrochloric acid. It is in the form of a yellowish, tasteless powder, having a faint odor of thymol. It is readily soluble in alcohol, ether, chloroform and olive oil, but insoluble in water, petroleum benzin and glycerin. It is used as an antiseptic dusting powder.

Thymol Urethane. *Thymoli Carbonas. Thymolcarbonic Ether.*—J. F. Pohl, by the same process by which guaiacol is converted into guaiacol carbonate, has produced from thymol a nearly tasteless, colorless, crystalline compound of neutral reaction, fusing at $49^\circ C.$ ($120.2^\circ F.$). It is slightly soluble in water, but is decomposed by the alkaline juices of the intestine, thymol being liberated. It is claimed that this substance is as effective as thymol against the *anchylostoma*, and, owing to its not dissolving in the stomach, is much less apt to produce disagreeable symptoms. (*A. J. P.*, March, 1901, 143.) *Dose*, for adult, thirty grains (2 Gm.) three times a day for four days, followed by brisk purgation.

Thymus Gland.—The close connection which exists between the development of the body and the thymus gland would suggest the use of the extract in *ricketts* and other diseases which occur especially during the developmental stage of life, and are accompanied by marked failure of nutrition. We know, however, of no studies made upon the subject. Without any apparent guiding principle the extract of the thymus has been used to a considerable extent in the treatment of *exophthalmic goitre*. The results appear to warrant the conclusion that the thymus gland possesses no specific action in that disease. That the thymus body has some activity seems to be indicated by the experiments of Svehla, who found that its intravenous injection produces a marked fall of blood pressure which he believes to be the outcome of vasomotor paralysis, and that large doses cause dyspnoea and collapse, ending in death. *Dose*, of extract, from three to five grains (0.2–0.32 Gm.) in capsules.

Tilia. *Linden Tree.*—The dried flowers of *Tilia europaea*, L., and of other species of *Tilia* (Fam. Tiliaceæ) are official in the German Pharmacopœia under the head of *Flores Tiliæ*. The flowers contain a colorless, fragrant, volatile oil. The bark has been said to contain a neutral body, *tiliadin*, and a glucoside *tiliacin*. (See *A. J. P.*, 1890; *P. J.*, 66, 105.) The infusion is used as a household remedy to relieve hysteria and indigestion.

Timbo.—This name is applied in Brazil to various sapindaceous plants, used as fish poisons. Among these is *Serjania curassavica*, Radlk. (*Paullinia pinnata*, L.), in which Stanislaus Martin (*B. G. T.*, xcii.) has found an alkaloid, *timbonine*; F. Pfaff has obtained from a timbo of unknown origin two alkaloids, *timboin* and *anhidrotimboin*, also an oily compound, *timbol*. (*A. J. P.*, Nov. 1891.)

Tin. (Sn. At. wt., 118.1.) *Stannum. Etain*, Fr. *Zinn*, G.—This was recognized in the old Edinburgh and Dublin Pharmacopœias, and in the U. S. of 1850, but is no longer official. It has, however, too long ranked among recognized remedies to be passed without notice. Tin is one of the metals which have been known from the earliest ages. It exists generally as an oxide (*tin stone* and *wood tin*), rarely as a sulphide (*tin pyrites*), and is by no means generally diffused. It is found in England, Spain, Germany, Bohemia, and Hungary, in Europe, and sparingly in some parts of the United States; in the island of Banca and the Peninsula of Malacca in Asia; in Bolivia, and at Durango in Mexico. The mines of Banca furnish the purest tin. The metal is extracted from the native oxide. When this occurs in its purest state, in detached roundish grains, called *stream tin*, the reduction is effected by heating with charcoal. When the common oxide, called *mine tin*, is reduced, it requires to be freed, by pounding and washing, from the adhering gangue, after which it is roasted to drive off sulphur, arsenic, and antimony, and finally reduced in furnaces by means of stone coal. The metal, as thus obtained, is called *block tin*, and is not pure. The purest kind of tin known in commerce is called *grain tin*. The world's production of tin in 1903 is given as 93,893 tons. The importations of block tin into the United States for the year 1903 amounted to 44,028½ short tons, valued at \$23,618,802, while the importations of tin andterne plate, which in 1889 amounted to 331,311 long tons, valued at \$21,726,707, in 1903 had diminished to 47,360 tons, valued at \$2,999,252.

Tin is a malleable, rather soft metal, of a silver-white color. It may be beaten out into thin leaves, called *tin foil*. It undergoes a superficial tarnish in the air. Its taste is slight, and when rubbed it exhales a peculiar odor. Its ductility and tenacity are small; when bent to and fro, it emits a crackling noise, which is characteristic. Its sp. gr. is 7.29, melting point $235^\circ C.$ ($455^\circ F.$), and it volatilizes at a white heat. It forms two oxides. The *stannous oxide*, SnO , is of a grayish-black color. When perfectly pure it has, according to Roth, a red color. *Stannic oxide*, SnO_2 , or *dioxide*, forms two hydrates, both being acids,—*stannic acid*, $SnO_3 \cdot H_2O$, and *metastannic acid*, $Sn_6O_{10} \cdot 5H_2O$, or $(H_2SnO_3)_5$.

The tin of commerce is often impure, being contaminated with other metals, introduced by

fraud or present in consequence of the mode of extraction from the ore. A high specific gravity is an indication of impurity. When its color has a bluish or grayish cast, the presence of copper, lead, iron, or antimony may be suspected. Arsenic renders it whiter, but at the same time harder, and lead, copper, and iron cause it to become brittle. Pure tin is converted by nitric acid into a white powder (*metastannic acid*), without being dissolved. Boiled with hydrochloric acid, it forms a solution which gives a white precipitate with potassium ferrocyanide. A blue precipitate with this test indicates iron, a brown one copper, and a violet-blue one both iron and copper. If lead be present, a precipitate will be produced by magnesium sulphate. The Malacca and Banca tin and the English grain tin are the purest kinds found in commerce. Banca tin, from analyses by Mulder, appears to be particularly pure, containing only one-twenty-fifth of one per cent. of foreign metals. Block tin and the metal obtained from Germany are usually of inferior quality.

Tin enters into the composition of bronze, bell metal, pewter, and plumber's solder. It is used also in making tin plate, which is sheet iron coated with tin, in making tin amalgam for silvering looking glasses, and in forming the solution of *stannous chloride* (*bichloride of tin*), a combination essential for the dyer's use. It is employed in fabricating various vessels and instruments useful in domestic economy and the arts. Being unaffected by weak acids, it forms a good material for vessels intended for boiling operations in pharmacy. A false tin foil is considerably used at present, made by coating lead with tin, and then rolling it out into thin sheets. As tin foil is employed for enclosing medicinal powders and perishable articles of food and medicine, care should be taken not to use this substituted preparation.

STANNI PULVIS. *Powder of Tin.*—For directions for making, see 16th edition *U. S. D.* Powder of tin was used as a mechanical anthelmintic, but has very properly gone out of vogue. The dose is half an ounce, mixed with molasses, given for several successive mornings, and then followed by a brisk cathartic purge. In the *J. P. C.*, 4e sér., xix. 78, is reported a death believed to have been caused by tin. Pattengo (*A. E. P. P.*, xvii., 1886) confirms the old statement of Orfila that the metal is of no therapeutic value. Three-fourths of a grain of the chloride intravenously injected into a dog suffice to cause trembling, Cheyne-Stokes respiration, opisthotonos, and death. Stannous chloride, or chloride of tin, is a violent irritant and mild caustic. Chemically pure tin, given internally, is probably not absorbed. (See 16th edition *U. S. D.*)

Tinospora. *Br. Add.*—"The dried stem of *Tinospora cordifolia*, Miers (Fam. Menispermaceæ), collected in the hot season." *Br. Add.* *Tinospora* has long been used in India as a medicine and in the preparation of a starch known as *gilæ-ka-sot* or as *palo*. It is said to be a tonic, antiperiodic, and a diuretic. Flückerger obtained from it traces of an alkaloid and a bitter glucoside. The *Br. Add.* recognizes an infusion (*Infusum Tinosporæ*, *Br. Add.*, two ounces to the pint), dose, one-half to one fluidounce (15–30 Cc.); a tincture (*Tinctura Tinosporæ*, *Br. Add.*, four ounces to the pint), dose, one-half to one fluidrachm (1.8–3.75 Cc.); and a concentrated solution (*Liquor Tinosporæ Concentratus*, *Br. Add.*), dose,

one-half to one fluidrachm (1.8–3.75 Cc.). *Tinospora crispa*, Miers, which is abundant in the Philippines, is used freely by the natives under the name of *makabuhay* (that is, "You may live") as a panacea especially valuable in general debility, in chronic rheumatism, and in malarial fevers. It may be prepared in the same way and given in the same doses as *Tinospora cordifolia*.

Tissa. *Tissa rubra* (L.), Brit.—*Arenaria rubra*, L., is a native of Malta, Sicily, and Algiers, and has long been used as a popular remedy in diseases of the bladder. It was shown by F. Vigier (*J. P. C.*, 1879, ii. p. 371) to contain a resinous aromatic substance which is probably its active principle. It is strongly recommended by Bertherand in calculous diseases and acute and chronic cystitis. The aqueous extract may be given in doses of thirty grains (2.0 Gm.); or the fluidextract, dose, a fluidrachm (3.75 Cc.), three or four times a day.

Tobacco. *Tabacum.* *U. S.* 1890. *Nicotiana Tabacum*, L.—An annual plant with a large fibrous root, and an erect, round, hairy, viscid stem, which branches near the top, and rises from three to six feet in height. The leaves are numerous, alternate, sessile, and somewhat decurrent, very large, ovate-lanceolate, pointed, entire, slightly viscid, of a pale green color, and are the part employed. The seeds, examined by F. M. Brandt, yielded no narcotic principle, though a protein-like substance contained in them was thought by its decomposition to produce nicotine (*Neues Jahrb. für Pharm.*, xxi. 42). William Procter also failed to find nicotine in the seeds. (*Proc. A. Ph. A.*, 1858, 296.)

There is good reason to believe that this plant is a native of tropical America, where it was found by the Spaniards upon their arrival. It is at present cultivated in most parts of the world, and nowhere more abundantly than within the limits of the United States. Virginia is, perhaps, the region most celebrated for its culture. The young shoots, produced from seeds thickly sown in beds, are transplanted into the fields during the month of May, and set in rows with an interval of three or four feet between the plants. Through the whole period of its growth the crop requires constant attention. The development of the leaves is promoted by removing the top of each plant and thus preventing it from running into flower and seed. The harvest is in August. The ripe plants, having been cut off above their roots, are dried under cover, and then stripped of their leaves, which are tied in bundles and packed in hogsheads. While hung up in the drying houses, they undergo a curing process, consisting in exposure to a considerable degree of heat, through which they become moist, or, in other words, are said to sweat, after which they are dried for packing.

Two varieties of this species are mentioned by authors, one with narrow, the other with broad leaves; but they do not differ materially in properties. Great diversity in the quality of tobacco is produced by difference of soil and mode of cultivation, and several varieties are recognized in commerce. Other species also of *Nicotiana* are said to be cultivated, especially *N. rustica*, L., which is said to have been the first introduced into Europe, and is thought to have been cultivated by the aborigines of this country, as it is naturalized near the borders of some of our small Northern lakes. The *N. quadrivalvis* of Pursh affords tobacco to the Indians of the Missouri and Columbia Rivers; and *N. fruticosa*, a native of China, was probably cultivated in Asia before the discovery

of this continent by Columbus. The latter species is said by John Le Conte to be that from which the best Cuba tobacco is obtained.¹ (*A. J. P.*, 1859.) Besides these there are *N. Persica*, L., cultivated in Persia; *N. repanda*, Willd., cultivated in Central and Southern North America; *N. Bigelovii*, Wats., of North America; and certain cultivated forms of *N. Tabacum*, L., which have been given by some authors specific rank.

The total annual production of tobacco throughout the world at present is estimated at 1,000,000 tons, of which Asia furnishes 350,000, America 300,000, Europe 250,000, and the rest of the world 100,000 tons. (*Zeit. für Angew. Chem.*, 1905, p. 1623.)

Tobacco, as it occurs in commerce, is of a yellowish-brown color, a strong narcotic penetrating odor which is wanting in the fresh leaves, and a bitter, nauseous, and acrid taste. These properties are imparted to water and alcohol. They are injured by long boiling, and the extract is, therefore, relatively feeble. An elaborate analysis of tobacco was made by Vauquelin, who discovered in it among other ingredients, an acrid, volatile, colorless liquid, slightly soluble in water, very soluble in alcohol, and supposed to be the active principle. It was separated by a complicated process, of which, however, the most important step was the distillation of tobacco juice with potassium hydroxide. In the results of this distillation Vauquelin recognized alkaline properties, which he ascribed to ammonia, but which were, in part at least, dependent upon the acrid principle above mentioned. To this principle the name of *nicotine* was given; but its alkalinity was not ascertained till a subsequent period. Another substance was obtained by Hermstädt by simply distilling water from tobacco and allowing the liquid to stand for several days. A white crystalline matter rose to the surface, which upon being removed was found to have the odor of tobacco, and to resemble it in effects. It was fusible, volatilizable, similar to the nicotine of Vauquelin in solubility, and without alkaline or acid properties. It was called *nicotianin* by Hermstädt, and appears to partake of the nature of volatile oils. Flickiger, who made a study of this nicotianin, is of the opinion that it is simply a fatty acid contaminated with a little volatile oil. (*Pharmacographia*, 2d ed., p. 468.) According to Landerer, it occurs only in dried tobacco leaves. It forms white crystalline scales of a delicate tobacco-like odor, a bitter taste, and a neutral reaction. It is only slightly soluble in water, soluble in ether and alcohol. According to an analysis of Barral (*C. R. A. S.*, 21, p. 1376), it has the formula $C_{23}H_{32}N_2O_8$. Barral states, moreover, that when distilled with strong solution of potassium hydroxide it yields nicotine.

Two German chemists, Posselt and Reimann, subsequently analyzed tobacco, and ascertained the

alkaline nature of its active principle, which, however, neither they nor Vauquelin obtained in a state of purity. The nicotine obtained by Vauquelin and by Posselt and Reimann was a colorless, volatile liquid, and, as subsequently ascertained by Henry and Boutron, was in fact an aqueous solution of the alkaline principle in connection with ammonia. It was reserved for these chemists to obtain nicotine in a state of purity. It exists in tobacco combined with an acid in excess, and in this state is not volatile. It is easily extracted from tobacco by means of alcohol or water as a malate, from which the alkaloid can be separated by shaking it with caustic lye and ether. The ether is then expelled by warming the liquid, which finally has to be mixed with slaked lime and distilled in a stream of hydrogen, when the nicotine begins to come over at about 200° C. (392° F.). The percentage of nicotine in tobacco varies considerably,—from 1.62 per cent. in Havana tobacco and 2 per cent. in Maryland tobacco to 6 per cent. in Virginia tobacco and 8 per cent. in Kentucky tobacco. For a mode of estimating the proportion of nicotine in tobacco, see *P. J.*, Dec. 1873, 442.² For an analysis of the ashes of Virginia tobacco, by McD. Irby of New Orleans, and J. A. Cabell of Virginia, see *Chem. News* (Sept. 4, 1874, 117).

Nicotine. (*Nicotina* or *Nicotia*.)—This is a colorless or nearly colorless fluid, of the sp. gr. 1.027, boiling at 247° C. (476.6° F.), and not solidifying at -10° C. (14° F.); having a faint odor when cold; of an exceedingly acrid, burning taste, even when largely diluted; entirely volatilizable, and, in the state of vapor, very irritant to the nostrils, with an odor recalling that of tobacco; inflammable; very soluble in water, alcohol, ether, the fixed oils, and oil of turpentine; strongly alkaline in its reaction, and capable of forming crystallizable salts with the acids. These salts are deliquescent, having a burning and acrid taste, and, like the salts of ammonia, lose a portion of their base by heat. Its formula is $C_{10}H_{14}N_2$, and it is recognized as a *hexahydrodipyridyl*, $C_{10}H_8(H_6)N_2$. While nicotine has not been prepared synthetically as yet, two isomeric bases, *isonicotine* and *nicotidine*, have been prepared. On treatment with oxidizing agents, nicotine yields *nicotinic* or β -pyridinecarboxylic acid, $C_8H_4N.COOH$. In its action on the animal system it is one of the most virulent poisons known. A drop of it, in the state of concentrated solution, is sufficient to destroy a dog, and small birds perish at the approach of a tube containing it. Tannin forms with it a compound of but slight solubility, and might be employed as an antidote. Nicotine exists in tobacco in small proportion; it has been found in the seeds, and, in very small proportion, in the root. There can be little doubt that tobacco owes its activity to this alkaloid, which has also been criminally employed as a poison. (*N. Y. Jour. of Med.*, N. S., ix.) Nicotine has the remarkable property of resisting decomposition amid the decaying tissues of the body, and was detected by Orfila in the bodies of animals destroyed by it two or three months after their death. Mayer concluded from his experiments that nicotine is the active principle in all parts of the plant both before and after curing. (*Proc. A. Ph. A.*, 1865.)

¹ There is reason for believing that the official species is a more exclusive source of the commercial tobacco than is indicated by the text, and also in the *Pharmacographia*, where it is stated that *N. rustica* furnishes *East India Tobacco* and the kinds known as *Latakia* and *Turkish Tobacco*, *N. Persica* the tobacco of Shiraz, and *N. repanda* a much valued Havana tobacco. *Latakia* tobacco seems, however, to be the product of the official plant, and Senator Vidal asserts that *N. repanda* is not found in Cuba, *N. Tabacum* being the only species there cultivated. (*P. J.*, viii, 710.) Again, the Persian and Turkish tobacco sold under the name of *tumbeki* of commerce, which has been variously attributed to *N. Persica* and to *N. rustica*, is in all probability the product of *N. Tabacum*. (*Kew Bulletin*, April, 1891.)

² For Liecke's and Schloessing's methods of estimating nicotine, see 17th edition *U. S. D.*, p. 1346. For Kosutany's method, see *Zeit. An. Chem.*, 1893, 277.

Pictet and Rotch (*A. J. P.*, 1902, p. 292) have isolated three new alkaloids from tobacco. The first of these is a liquid boiling at 266° to 267° C. (510.8°–512.6° F.), to which the name *nicotine*, and the formula $C_{10}H_{12}N_2$, has been given; the second *nicotelline*, $C_{10}H_8N_2$, has a boiling point of over 306° C. (583° F.), and is solid at ordinary temperatures, crystallizing from alcohol in white prismatic needles, and the third is very volatile, found admixed with nicotine, and has not as yet been satisfactorily studied.

Vohl and Eulenberg (*P. J.*, Jan. 1872, p. 567) made an interesting analysis of tobacco smoke. The smoke analyzed was from strong tobacco, containing 4 per cent. of nicotine. Notwithstanding this large proportion of nicotine, none of it was found in the smoke, the authors differing in their results from most previous observers. The subject has been reinvestigated by R. Kissling (*Ding. Polyt. Journ.*, 244, 64), who has shown that Vohl's conclusion as to the non-existence of nicotine in tobacco smoke is due to that chemist having overlooked the fact that the alkaloid is decomposed by warm potassium hydroxide, a reaction which has not met with general recognition.

When cigars were smoked, certain gases were given off, which, when collected and examined, proved to be oxygen, nitrogen, carbon dioxide, and marsh gas. The smoke was drawn first through a potassium hydroxide solution to collect acids, and then through diluted sulphuric acid to collect bases. With the alkaline solution, an oily substance appeared on the surface, having an almost intolerable odor of tobacco smoke, and from this was obtained, by distillation at a gradually increasing temperature, at first a liquid and oily product, and, at the temperature of 300° C. (572° F.), a substance which on cooling became a laminated mass. This, on being repeatedly crystallized from ether, assumed the appearance of pearly white scales, melting between 94° and 95° C. (201.2° and 203° F.), and of a higher boiling point than mercury. From these characters, as well as its percentage composition, this substance appears to be identical with the hydrocarbon ($C_{10}H_{12}$) discovered by Kraut. The oily distillate before this, having been purified by repeated treatment with potassium hydroxide and sulphuric acid, had a sp. gr. 0.8 to 0.87, and from its percentage composition (92 or 93 C and 8 or 7 H) appears to be a mixture of different hydrocarbons belonging to the benzene or some analogous series. The potassium hydroxide solution, after the separation of the oils yielded, under appropriate treatment, a large amount of gas, consisting of carbon dioxide and hydrogen cyanide and sulphide; consequently the statement that tobacco smoke contains no cyanogen is a mistake. Upon a distillation of the potassium hydroxide solution after the addition of sulphuric acid, several acids were found in the distillate,—viz., acetic, propionic, butyric, and valeric, with a portion of creosote, more doubtfully caproic, caprylic, and succinic acids. Only the sulphuric acid solution now remained for examination. From this, which had become dark-colored and thick on standing, a *dark brown resin* was separated. By treatment with potassium hydroxide, ammoniacal vapors escaped, and a *brown oil* with the odor of tobacco smoke floated on the surface. From the residuary liquid, after distillation, saturation with potassium hydroxide, and redistillation, vapors escaped which proved to be ammonium chloride. After further treatment, for

which we refer to the original, the oily residue was divided by fractional distillation, and the whole series of picoline bases, analogous to the aniline bases, were obtained. The identities of the following were determined by their boiling point, percentage composition, and the composition of the double platinum salt: *pyridine*, C_5H_5N , boiling point 115° to 116° C. (239°–240.8° F.); *picoline*, C_6H_7N , boiling point 134° to 135° C. (273.2°–275° F.); *lutidine*, C_7H_9N , boiling point 155° C. (311° F.); *collidine*, $C_8H_{11}N$, boiling point 171.5° C. (341° F.) (isomeric with xylidine); *parvoline*, $C_9H_{13}N$, boiling point 187° to 188° C. (368.6°–370.4° F.) (isomeric with cumudine); *coridine*, $C_{10}H_{15}N$, boiling point 211° C. (411.8° F.); *rubidine*, $C_{11}H_{17}N$; and probably *viridine*, $C_{12}H_{19}N$, boiling point 251° C. (483.8° F.). No trace of nicotine was to be found. The authors experimented physiologically with only a mixture of those boiling below 160° C. (320° F.), and of those boiling between 160° and 250° C. (320° and 482° F.), and these were found, like nicotine, to cause contraction of the pupil, dyspnea, general convulsions, and death.

Thoms (*A. J. P.*, 1900, p. 227) has reported upon the composition of tobacco smoke, confirming most of the statements made above. He, however, obtained distinct quantities of phenols and a small quantity of furfural. In cigars from which the nicotine had been removed, no pyridine was found in the smoke.

When distilled at a temperature above that of boiling water, tobacco affords an empyreumatic oil, which Brodie proved to be a most virulent poison. It was official in the U. S. P. 1870, under the name of *Oleum Tabaci: Oil of Tobacco*. A single drop, injected into the rectum of a cat, occasioned death in about five minutes, and double the quantity, administered in the same manner to a dog, was followed by the same result. This oil is of a dark brown color and an acrid taste, and has a very disagreeable odor exactly resembling that of tobacco pipes which have been much used. It has been stated to contain nicotine. (*Ann. Ch. Phys.*, 3e sér., ix. 465.)

It is quite certain that tobacco leaves undergo considerable chemical changes during the processes of curing and preparation for use. Thus, the characteristic odor of ordinary tobacco is entirely different from that of the fresh leaves, and must be owing to the generation of a new volatile principle. It has also been asserted that the proportion of nicotine in prepared tobacco is greater than in the fresh. It has even been made a question whether nicotine exists at all in the fresh growing leaves; but this question has been experimentally decided in the affirmative by Procter (*Proc. A. Ph. A.*, 1858, p. 300), and Mayer of New York, has experimentally determined that the nicotine exists as largely in the plant before as after curing; indeed, he believes that it is somewhat diminished in the process, probably in part if not altogether by volatilization. (*Ibid.*, 1865.)

The distinguishing character of tobacco, as given in the Br. Pharm. 1885, is that when distilled with solution of potassium hydroxide it yields an alkaline fluid having the peculiar odor of nicotine and giving precipitates with platinum chloride and tincture of galls.

Medicinal Properties and Uses.—Tobacco is a powerful sedative poison, which is locally irritant. Snuffed up the nostrils, it excites violent sneezing and a copious secretion of mucus; chewed, it irritates the mucous membrane of the

mouth and increases the flow of saliva; when injected into the rectum, it sometimes operates as a cathartic;¹ and the alkaloid nicotine injected into the cellular tissue of animals evidently produces much pain. Moderately taken, it quiets restlessness, calms mental and corporeal inquietude, and produces a state of general languor or repose which has great charms for those habituated to the impression. In larger quantities, it gives rise to confusion of the head, vertigo, stupor, faintness, nausea, vomiting, and general depression of the nervous and circulatory functions, which, if increased, eventuates in alarming and even fatal prostration. The symptoms of its excessive action are severe retching, with the most distressing and continued nausea, great feebleness of pulse, coolness of the skin, fainting, and sometimes convulsions. We are singularly deficient in exact knowledge as to how these various symptoms are produced. In accordance with the experimental evidence at hand, the convulsions are spinal; and it seems well determined that the paralysis is due to a depressant action upon the motor nerve trunks, which immediately after death are found to be inexcitable. How the circulatory phenomena are brought about is not clear, but it would appear that the heart muscle is not itself directly affected, as Benham found that the direct application of the poison to the viscus does not arrest its pulsations.

The use of tobacco was adopted by the Spaniards from the American Indians. In the year 1560 it was introduced into France by the ambassador of that country at the court of Lisbon, whose name—Nicot—has been perpetuated in the generic title of the plant. Sir Walter Raleigh is said to have introduced the practice of smoking into England. In the various modes of smoking, chewing, and snuffing, the drug is now largely consumed in every country on the globe. It must have properties peculiarly adapted to the propensities of our nature to have thus surmounted the first repugnance to its odor and taste and to have become the passion of so many millions. When employed in excess, it enfeebles digestion, produces emaciation and general debility, and lays the foundation of serious nervous disorders. The most common of these is undoubtedly the disturbance of the innervation of the heart, with consequent palpitations and cardiac distress. Amaurosis and even color blindness are occasionally produced, and even insanity has been ascribed to chronic tobacco poisoning. In many cases of "nervous break-down" attributed to overwork, the excessive use of tobacco has certainly been an important etiological factor. In the form of snuff, tobacco is sometimes so much contaminated with lead, in consequence of being kept in leaden boxes, as to produce the poisonous effects of that metal. In different kinds of snuff Vogel found from 0.014 to 1.025 per cent. of lead. (See A. J. P., 1864, p. 422.)

Formerly much used as a relaxant, tobacco has been superseded by safer and more efficacious remedies, so that it is at present never employed in medicine, unless it be internally in *chronic asthma* and locally in *hemorrhoids* and in various spasmodic or painful affections. It should always be

borne in mind that its active principle is absorbed readily by the skin, and that serious or even fatal poisoning may result from its too free application to the surface of the body. A case of death is on record, occurring in a child eight years old, in consequence of the application of the expressed juice of the leaves to the head, for the cure of *tinea capitis*. Death has also been produced by the inhalation of the smoke.

From five to six grains (0.32–0.4 Gm.) of powdered tobacco will generally act as an emetic; but the remedy ought never to be used for such purpose.

Toddalia. Br. Add.—"The dried root-bark of *Toddalia aculeata*, Pers." (Fam. Rutaceæ.) This climbing shrub, known also as *Lopez root*, growing in the subtropical Himalayas and Ceylon, is a tonic stomachic, containing a resin and a volatile oil, which may be readily obtained from the leaves by distillation. This oil has the odor of citron peel, and a bitter aromatic taste. The British Addendum recognizes an *infusion* (*Infusum Toddalia*, Br. Add., two ounces to a pint), dose, one to two fluidounces (30–60 Cc.); also a *concentrated solution* (*Liquor Toddalia Concentratus*, Br. Add.), dose, from one-half to one fluidrachm (1.8–3.75 Cc.).

Tolypyrine. *Tolyantipyrin*, *Paratolyl-di-methyl-pyrazolon*. $C_6H_4CH_3N < \begin{matrix} N.CH_3.C.CH_3 \\ CO.CH \end{matrix}$

This compound occurs in colorless crystals soluble in water and alcohol, insoluble in ether, and is used like antipyrine as an antipyretic in doses of from eight to thirty grains (0.5–2.0 Gm.).

Tonga.—Tonga is a composition of unknown barks compounded by the natives of the Feejee Islands for medicinal purposes. The plants from which this remedy is derived are believed to be *Premna taiensis*, Schan. (Fam. Verbenaceæ), and *Epipremnum mirabile*, Schott. (*Rhaphidophora vitiensis*, Schott.) (Fam. Araceæ). (A. J. P., 1881, 439.) It was introduced to the notice of the medical profession by Sydney Ringer and Wm. Murrell of London, as a remedy for *neuralgia*. (L. L., ii. 1880.) The natives are said to steep the bundle as prepared by them for twenty minutes in half a tumblerful of cold water, and then, squeezing it dry, drink the infusion, preserving the bundle in a dry place for further use. A fluidextract has been put upon the market, and evidence of its value brought forward, but we have known a fluidrachm of this extract given every two hours for two days without obvious effect; the dose usually recommended is half a fluidrachm (1.8 Cc.).

Tonka Bean. *Fève Tonka*, Fr. *Tonka-bohnen*, G.—The seed of *Dipterya odorata* of Willd., the *Coumarouna odorata* of Aublet, a large tree growing in Guiana. The fruit is an oblong-ovate pod, enclosing a single seed, from an inch to an inch and a half long, from two to four lines broad, usually somewhat compressed, with a dark brown, wrinkled, shining, thin, and brittle skin, and a light brown oily kernel. The seed has a strong, agreeable, aromatic odor, and a bitterish, aromatic taste. Its active constituent is a crystallizable, odorous substance, called *coumarin* or *cumarin*, $C_9H_6O_2$, by Guibourt. It is the anhydride of *coumaric acid*, $C_9H_6O_3$. It is capable of sublimation; but, to obtain it in crystals in this way, a low temperature is necessary. (Waddington, P. J., 1868, 410.) This substance is sometimes found in a crystalline state, between the two lobes of the kernel. Coumarin appears

¹ *Enema Tabaci*, Br. 1867. *Enema of Tobacco*. This preparation, though no longer official, is still occasionally used: "Take of Leaf Tobacco twenty grains; Boiling Water eight fluidounces. Infuse in a covered vessel, for half an hour, and strain." Br. The whole quantity to be given at once.

to be a widely spread substance which has been found in many species of plants, notably in species of *Melilotus* (Fam. Leguminosæ) and *Trilisa odoratissima* (Walt.), Cass. (*Liatris odoratissima*, Willd.) (Fam. Compositæ), a plant sometimes used to protect woollens from moths. (A. J. P., 1859, 556; also 1899, 133; see also *Chem. Gaz.*, 1852; D. C., Nov. 1887.) Gössmann obtains coumarin in the following manner. The beans, cut finely, are heated for a long time with an equal bulk of alcohol of specific gravity 0.863, nearly to boiling, and, the tincture being decanted, the residue is treated in the same manner. The tinctures are mixed, the alcohol distilled off until turbidness appears, when four times the bulk of water is added, which precipitates coumarin and fatty matter. The precipitate is then heated to boiling, and the liquid passed through a moistened filter. The fatty matter remains on the filter, and the hot solution which passes deposits the coumarin on cooling. More may be obtained by concentrating the liquid, and may be purified by animal charcoal. One pound of the beans yielded 108 grains of coumarin. (*Ibid.*, 1856, 211.) Coumarin has been prepared synthetically by heating salicylic aldehyde with sodium acetate and acetic anhydride, whereby *acetocoumaric acid* is formed, which decomposes further into acetic acid and coumarin. It has also been obtained by the action of phenol upon malic acid. Tonka bean is used to adulterate tincture and extract of vanilla and to flavor snuff, being either mixed with it in the state of powder or put entire into the snuff box. Coumarin adulterated with acetanilide has been found in the market. (*Schim. Rep.*, 1893, 67.) Köhler (*Ch. M. W.*, 1875, 869, 881) finds that coumarin is a decided narcotic, and is at first stimulant, afterwards paralyzant to the heart. (See also C. Levaditi; *Centrib. f. allgem. Path.*, xii, 1901.) The fluidextract of the bean has been used with asserted advantage in *whooping cough* in doses equivalent to from five to eight grains (0.32–0.5 Gm. for children five years old. (A. J. P., 1869, 27.)

Tormentilla. *Rhizoma Tormentillæ*, P. G. *Tormentille*, Fr. *Tormentillwurzel*, G. *Tormentilla*, It. *Tormentila*, Sp.—Various species of the rosaceous genus *Potentilla* have been employed in medicine. (See A. J. P., 1875, 109.) It is asserted (*Ibid.*) that our common *P. canadensis*, L., is a valuable sudorific and diuretic.

Potentilla Tormentilla, Neck. (*Tormentilla erecta*, L., *T. officinalis*, Curt.)—The tormentil, or septfoil, which was formerly in the Secondary List of the U. S. Pharmacopœia, is a small perennial plant of Europe. All parts of the plant are astringent, especially the root, which is the part employed. The root of tormentil is cylindrical and rounded, rather larger above than at the lower extremity, an inch or two in length, about as thick as the finger, knotty, sometimes contorted, brown or blackish externally, and reddish within. It has a slight aromatic odor and a very astringent taste. Tannin is an abundant constituent. There is also a red coloring principle, soluble in alcohol, but insoluble in water. Besides these ingredients Meissner found resin, cerin, myricin, gummy extractive, gum, extractive, lignin, water, and a trace of volatile oil. Tormentil has since been chemically examined by Rembold, who obtained tormentilla red by boiling the tannin of the root (*tormentillanic acid*, $C_{26}H_{22}O_{11}$) with sulphuric acid. It

has the same composition as rhatany red, and yields the same products of decomposition when fused with potassium hydroxide. He also obtained *kinovic acid*, $C_{24}H_{32}O_8$, from the root by boiling it with milk of lime, adding hydrochloric acid to the decoction, boiling the precipitate with solution of barium hydroxide, decomposing again by hydrochloric acid, dissolving the precipitate in alcohol, decolorizing with animal charcoal, filtering, concentrating, and crystallizing. Small quantities of *ellagic acid*, $C_{14}H_6O_8$, were also noted by him. (A. J. P., 1868, 311; from *Ann. Chem.*, cxliv, 5.) The root is said to be used for tanning leather in the Orkneys and Western Islands of Scotland, and for staining leather red by the Laplanders. Tormentil is a simple and powerful astringent, applicable to all cases of disease in which this class of medicines is indicated. It may be given in substance, decoction, or extract. The dose of the powder is from thirty grains to a drachm (2.0–3.9 Gm.).

Toxicodendron capense, Thunb. (*Hydnangea globosa*, Lam., *H. capense*, Peis.) (Fam. Euphorbiaceæ.)—The fruits of this South American species are said to be used for the poisoning of hyenas. They have been investigated by Arthur Baron von Engelhardt (*Kobert's Arbeiten*, 1892), who finds in them a chemically neutral, bitter principle, *hydnanchin*, which is a powerful poison, resembling in its physiological action strychnine, from which, however, it differs in that it powerfully affects the cerebrum. The convulsions which it produces are of central origin, the poison having no action upon the nerve trunks or the muscles.

Toxylon. *Toxylon pomiferum*, Raf. (*Maclura aurantiaca*, Nutt.) (Fam. Moraceæ.) *Osage Orange*.—The bark of the root of this tree, which is indigenous in the Southern United States, is said to be considerably used in making a yellow dye. Alex. King has found in it *morio* and *moriannic acids*. (A. J. P., xlv, 257.)

Tragoponic Acid.—This was found by Rademaker and Fisher in the seeds of *Tragopogon porrifolius*, L. (Fam. Compositæ.) *Salsify*, more commonly known as *oyster plant*, is the plant which furnishes the edible root. (See *Nat. Drug.*, July 23, 1886, 47.)

Traumatol. *Iodocresine*. *Iodocresol*. C_6H_5I . $(CH_3)OH$.—This occurs as a purplish-red or yellow powder; it is obtained by acting on cresol with iodine, and is used as a substitute for iodoform.

Tribromallyl. *Tribromhydrinum*.—This is a colorless liquid, having a specific gravity of 2.436, freely soluble in ether. It has been recommended by De Fleury for *hysteria*, *asthma*, and similar nervous affections, in the dose of five drops in capsules from two to four times a day.

Tribromphenol. $C_6H_2Br_3.OH$.—Tribromphenol is prepared by shaking a solution of phenol with bromine water. It occurs in the form of soft, white, colorless needles, melting at 95° C. (203° F.), and subliming undecomposed at a higher temperature. It is soluble in alcohol, ether, and chloroform, and soluble with difficulty in glycerin, liquefied phenol, water, and weak alcohol. In caustic alkaline solutions it is readily soluble, and from them it is separated unaltered by acids.

Tribromphenol has been strongly recommended by Grimm for use in *antiseptic surgery*. He finds that a gauze containing a 2 per cent. solution of the compound, when saturated with blood

serum or urine, will remain perfectly odorless for fourteen days, and that a half per cent. solution of it will kill the bacteria of putrefaction in an hour.

Tribromphenol-Bismuth. *Xeroform.* ($C_6H_2Br_3O$) $_2$ BiOH + Bi $_2$ O $_3$.—This is a yellowish-green, insoluble, almost odorless and tasteless powder, which, according to its manufacturer, is a chemical combination of equal amounts of bismuth and tribromphenol, containing about 50 per cent. of bismuth oxide. It has been especially recommended by Hueppe (*B. K. W.*, 1893) as a specific in *cholera*, and has been used as an intestinal antiseptic in acute and chronic *enteritis* and in various functional and organic diseases of the alimentary canal.

Xeroform has also been recommended by E. Heuss (*Th. M.*, April, 1896) as a local antiseptic remedy for surgical use, especially valuable in the treatment of *burns*, *infected wounds*, *ulcers*, and other conditions for which iodoform is commonly employed. It does not alter under the influence of light, and since it is not decomposed by a temperature of 120° C. (255° F.), can be readily sterilized.

Dose, eight to fifteen grains (0.5–1.0 Gm.).

Tribromphenol Bromide. $C_6H_2Br_3OBr$.—E. W. Lewis finds (*Proc. Chem. Soc.*) that the melting point usually attributed to this substance 47.8° C. (118° F.), is much too low, and that it may be raised to 148° to 149° F. (64.4°–65° C.) by recrystallizing the compound from ethyl acetate; moreover, while, as usually stated, the substance of low melting point gives off bromine on heating at about 125° F. (51.7° C.), the purified material begins to lose bromine before melting at about 145° F. (62.8° C.). Tribromphenol bromide is made by adding 2 to 4 Gm. of phenol dissolved in water to bromine water containing 10 Gm. of bromine. After each addition of phenol the bottle is vigorously shaken, and when all of the phenol is added the mixture is set aside in a dark place for three days; the precipitate is then collected, drained on a porous earthenware tile and dried over sulphuric acid; the precipitate is then dissolved in warm ethyl acetate and the solution on cooling deposits the crystals. The crystals of tribromphenol bromide belong to the orthorhombic system. It forms citron-yellow scales which are insoluble in water, ether, cold alcohol, and alkalis. On boiling with alcohol it is decomposed and tribromphenol results.

Triferrin, or *paranucleinate of iron*, contains about 22 per cent. of iron as well as 2½ per cent. of organically combined phosphorus and is prepared from casein of cow's milk by digestion and precipitation by means of ferric salts. Triferrin is freely and completely soluble in a weak solution of sodium hydroxide, but it is insoluble in diluted hydrochloric acid having the acid strength of normal gastric juice. *Dose*, five grains (0.32 Gm.).

Trigonella. *T. Fœnum-græcum*, L. *Fenugreek.* *Semen Fœnugræci*, P. G. *Bockshornsamén*, G. A European annual leguminous plant cultivated in France and Germany for its seeds. These are oblong-cylindrical, somewhat compressed, obliquely truncated at each extremity, one or two lines in length, brownish yellow externally, yellow internally, and marked with an oblique furrow running half their length. They have a strong peculiar odor, and an oily, bitterish, farinaceous taste, and contain fixed and volatile oils, mucilage, bitter extractive, and a yellow coloring substance. E. Jahns (*Ber. d. Chem. Ges.*, xviii. 2518-2523)

has obtained *choline*, $C_5H_{15}NO_2$, and *trigonelline*, $C_7H_7NO_2$. The yield of the former was 0.05 per cent., and of the latter 0.13 per cent. Trigonelline is isomeric and probably identical with pyridinebetaine. By heating trigonelline with concentrated solution of potassium hydroxide, a distillate is obtained which appears to contain pyridine. An ounce of the seeds, boiled in a pint of water, renders it thick and slimy. They yield the whole of their odor and taste to alcohol. On the continent of Europe they are employed in the preparation of emollient cataplasms, enemata, ointments, and plasters. They are never used internally for human beings, but the ground seeds are used to an enormous extent in the manufacture of cattle powders or condition powders.

Trillium, *Beth Root.* *Birth Root.* *Wake Robin.* *Trillium*, Fr., G.—The indigenous species, *T. erectum*, L., is said to have been employed by the aborigines, and also used by the early settlers; it still has some vogue under the name of *beth root* as an astringent and tonic expectorant; also in *hemorrhages* and to hasten *parturition*, and as a local irritant in *skin diseases*. *Dose*, of powdered root, a drachm (3.9 Gm.) three times a day. E. S. Wayne found in it a substance supposed to be saponin. It is said also to contain volatile oil and tannic acid. D. J. Prendergast believes that the *Trillium erectum*, L., contains a glucoside similar to convallamarin. (*Am. Drug.*, Nov. 1887.) For details, see 16th edition *U. S. D.* Vivian I. Reid (*A. J. P.*, 1892, 67) found a small quantity of fixed oil, saponin to the extent of 4.86 per cent., and an acid crystalline principle which is colored purplish-brown by sulphuric acid, and light green with sulphuric acid and potassium dichromate.

Trimethylamine. *Propylamine.* *Seocaline.* *Triméthylamine*, Fr. *Trimethylamin*, G.—Wertheim in 1850 prepared from narcotine a substance having the formula C_3H_9N , and gave it the name *metacetamine*. In the same year Anderson prepared from codeine, and Hofmann from methyl compounds, substances having the same formula, giving them respectively the names of propylamine and trimethylamine. Other chemists have obtained similarly constituted principles from cod liver oil, ergot, herring pickle, putrid calf's blood, etc., and have even found them in saline combination in the flowers of *Cratægus Oxyacantha*, L., *Sorbus Aucuparia*, L., and one or more species of *Chenopodium*. Under the name of propylamine some of these principles were introduced into medicine by Awenarius of St. Petersburg, and met for a time with considerable favor; so that several processes for preparing propylamine were published before the 13th edition *U. S. D.* Since that time it has been very clearly shown that these various substances, although containing the same number of atoms, have them differently arranged, are consequently possessed of diverse properties, and are hence only isomeric. The material obtained from herring pickle and other sources and sold as propylamine is indeed not propylamine at all, but a more or less impure solution of trimethylamine; it is, in truth, doubtful whether propylamine has ever been procured from a natural source or made in any other way than by treating propyl iodide with ammonia. Both principles are derived ammonias or amines, but propylamine is a primary compound ammonia (monamine), and trimethylamine is a tertiary compound ammonia (triamine). In the first body the nitrogen

is combined with two atoms of hydrogen and one propyl group, C_3H_7 , in the second with three methyl groups, $(CH_3)_3$.

The physical differences are very marked. Thus propylamine boils at $49^\circ C.$ ($120.2^\circ F.$), trimethylamine at $9.3^\circ C.$ ($48.7^\circ F.$). The commercial propylamine contains other ammonia compounds besides trimethylamine, the latter substance indeed being sometimes present in very small quantity. Trimethylamine is made on a large scale at present by the destructive distillation of the "vinasses," or residues of beet root molasses. For other processes, see 16th edition *U. S. D.*, p. 1944.

Brieger has shown that choline, neuridine, and trimethylamine are among the early products of albuminoid decomposition in the human cadaver, and are then followed by other and more poisonous bodies of the ptomaine class.

The best form of trimethylamine for use is probably the hydrochloride, which may be prepared in a state of purity as a very deliquescent salt, crystallizing in long needles. To form the chloride naturally the distillatory products in Perret's process may be received into hydrochloric acid and separated from any ammonium chloride by means of absolute alcohol. *Commercial propylamine*—i.e., impure solution of trimethylamine—is a colorless transparent liquid, of a characteristic odor, usually attended by some pungency, which may possibly be ascribed to the ammonia frequently mixed with it. It is soluble in water and alcohol, has a strong alkaline reaction, and forms crystallizable salts with the acids. If the end of a glass rod, previously dipped into hydrochloric acid, be held over the open mouth of a vial containing it, a white cloud of the chloride will be seen, as in the case of ammonia. *Pure propylamine* is said to be a perfectly clear, strongly refractive fluid, with the odor of ammonia; a boiling point of $49^\circ C.$ ($120.2^\circ F.$); a sp. gr. at $20^\circ C.$ ($67^\circ F.$) of 0.7186; inflammable; miscible with water. With hydrochloric acid it makes a deliquescent salt, soluble in alcohol, forming with platinum chloride a double salt, which crystallizes in large, dark, golden-yellow clinorhombic plates, somewhat soluble in hot water and alcohol. *Pure trimethylamine* is a gas at ordinary temperatures.

Locally applied, trimethylamine acts as a powerful irritant or, if in sufficient concentration, even as a mild caustic. According to Laborde, in its physiological action it resembles the ammonium chloride or carbonate, though differing in not causing convulsions in animals fatally poisoned with it. (*M. T. G.*, 1874, 241.) The chloride was found to act in the same way as the trimethylamine, but to be scarcely more than half as powerful. Combemale and Brunelle have found that the drug is a powerful stimulant to the salivary gland. Given to man, trimethylamine acts chiefly as a violent gastro-intestinal irritant, the dose of half a drachm of the commercial article, even if freely diluted, usually producing distinct effects upon the stomach and the intestines. It has been found to act as a depressant to the circulation, but Laborde affirms that unless given in such dose as to pro-

duce serious results from its local action, it increases both in man and animals the arterial pressure. In 1854 it was brought forward by Awenarius of St. Petersburg, Russia, as a specific in *rheumatism*, and by other Continental physicians some confirmation of the original statements was afforded. Extensive trial made with the remedy in Philadelphia and elsewhere this side of the Atlantic soon led to its abandonment, and at present the remedy has passed entirely out of vogue. Awenarius prescribed a mixture of twenty-five drops of propylamine with six fluidounces of distilled water, flavored if necessary with sugar and oil of peppermint; of this he gave a tablespoonful every three hours, taking care that the drug was pure and freshly prepared. (*Ann. Ther.*, 1859.) In France, where the chloride was preferred, the following was a favorite formula: Trimethylamine chloride ten grammes, tincture of orange peel twenty-eight grammes, syrup nine hundred and seventy grammes. A tablespoonful contains about three and one-half grains. The dose of trimethylamine chloride is from eight to fifteen grains (0.5–1.0 Gm.).

Triosteum. *T. perfoliatum*, L. *Horse Gentian*. *Bastard Ipecac.* *Tinker's Weed.* *Fever Root.* *Feverwort.* *Wild Ipecac.* *Racine de Trioste*, Fr. *Dreisteinwurzel*, G. (Fam. Caprifoliaceæ.)—This plant is found in most parts of the Eastern United States, preferring a limestone soil and shady situations. The rhizome or root, the part used, is horizontal, long, about three-quarters of an inch in diameter, thicker and tuberculated near the origin of the stem, of a yellowish or brownish color externally, whitish within, and furnished with fibres which may be considered as branches of the main root. When dry it is brittle and easily pulverized. On microscopic examination, numerous crystals of calcium oxalate are to be seen. It has a sickening odor, and a bitter, nauseous taste. It is said to contain an alkaloid which Andree believed to be identical with emetine, but which Hartwich has shown to be different. It yields its active properties to both water and alcohol. Triosteum is cathartic, and in large doses emetic, and perhaps diuretic. The bark of the root may be given in doses of twenty to thirty grains (1.3–2.0 Gm.), or the extract in half the quantity. For uses, see *A. J. P.*, 1891, 326.

Triphenin. *Propionyl-phenetid.* $C_6H_4.C_2H_5O.NH.(CH_3.CH_2.CO)$.—A homologue of phenacetin made by boiling a mixture of parphenetid with propionic acid; it forms colorless, odorless crystals, fusing at $120^\circ C.$, of feebly bitter taste, soluble in 2000 parts of water.

Triphenin has been used to a very limited extent as an antipyretic in *typhoid fever*, *pneumonia*, and other acute affections, and also as an analgesic for nervous pains. Its range of action is precisely that of phenacetin. It is stated that it acts promptly, mildly, and without untoward secondary effects. Dose, eight to fifteen grains (0.5–1.0 Gm.).

Tripoli. *Terra Tripolitana*.—An earthy mineral, of a whitish, yellowish, or pale straw color, sometimes inclining to red or brown, usually friable, often adhesive to the tongue, and presenting the aspect of argillaceous earth, though differing from clay by the roughness and hardness of its particles, and by not forming a paste with water. The *Venice tripoli* is said to come from Corfu. Tripoli is sometimes artificially prepared by calcining certain argillites. It is used for cleaning and polishing metals.

Trompatila.—This is the stem and branches of *Bowardia triphylla*, Salisb. (Fam. Rubiaceæ), a Mexican plant used by the natives for hydrophobia. (A. J. P., 1874, 51.)

Tulipine.—An alkaloid extracted from the garden tulip. It is said to be a cardiac poison, with remarkable sialagogue properties. (Nouv. Rem., 1886.) Under the name of *chelin* there has been put upon the market a brownish thick extract-like substance of an agreeable odor, easily soluble in water, said to be derived from the bulb of the tulip and to be non-poisonous. It has been highly recommended by H. Heyman as a soothing application in various forms of inflammatory skin diseases. (D. M. W., August, 1902.)

Tumenol.—A dark brown or brownish-black liquid, of a syrupy consistence, which is made from bituminous shale oils. These are agitated with sodium hydroxide solution to remove phenols and then with sulphuric acid to remove pyridine and other bases. The oil is then treated with fuming sulphuric acid. The dark syrupy liquid which separates is washed with water and dissolved in sodium hydroxide. From this solution ether extracts *tumenol oil*. Hydrochloric acid, on the other hand, if added to the sodium hydroxide solution, throws down *tumenol-sulphonic acid*. A mixture of these two substances constitutes *tumenol venale*, a soft, resinous, odorless mass. A. Neisser (D. M. W., 1891) highly commends *tumenol* as a local application in *eczema*, and as having extraordinary powers over the itching of *prurigo*, *parasitic dermatitis*, and other skin affections. He uses a lotion made with equal parts of ether, rectified spirit, and water or glycerin, and 10 per cent. of *tumenol*.

Turpeth. *Turpethum*, Br. Add.—“The dried root and stem of *Ipomœa Turpethum*, R. Br.” (*Operculina Turpethum* (L.), Peter.) (Fam. Convolvulacæ.) This plant, which grows throughout India and Ceylon, has long been used not only in India, but also to some extent by the Arabs and in Europe. According to Mèrat and De Lens, the root itself formerly came into commerce, but at present turpeth “consists of the root and stem of the plant cut into short lengths, usually from one-half to two inches (one and a quarter to five centimetres) in diameter; the central woody portion is often removed by splitting the bark on one side. The exterior surface has a twisted rope-like or columnar appearance due to deep longitudinal furrows, and is of a dull gray color; a transverse section shows a porous central column surrounded by a broad cortical portion, the section is of a pale yellowish-white color, the cortex sometimes being darker. The fracture is short in the cortex and fibrous in the central portion. The drug has a faint odor and a nauseous taste, which is perceptible only after it has been some time in the mouth.” Br. Add.

Boutron-Chalard found in turpeth root, resin, a fatty substance, volatile oil, albumen, starch, a yellow coloring matter, lignin, salts, and ferric oxide. (J. P. C., viii. 121.) The root contains 10 per cent. of resin. (Andouard, Ann. Thér., 1866, 118.) According to Spirgatis this resin is a glucoside, *turpethin*, $C_{76}H_{128}O_{36}$, like that of other Convolvulacæ, insoluble in ether, but soluble in alcohol, to which it imparts a brown color not removable by animal charcoal. To obtain it pure, the alcoholic solution is concentrated; the resin precipitated by, and afterwards boiled with, water, then dried, reduced to powder, digested with ether, and finally redissolved by absolute

alcohol and thrown down by ether. After being treated several times in this way, it is obtained in the state of a brownish resin, yielding on pulverization a gray powder, which strongly irritates the mucous membrane of the nostrils and mouth, and is fusible at 182.2° C. (360° F.). It is inflammable, burning with a smoky flame and emitting irritant vapors. With strong bases it acts like jalapin, takes up water, and is transformed into a soluble acid, *turpethic acid*, $C_{34}H_{56}O_{18}$, while with dilute acids it is decomposed into *turpetholic acid*, $C_{16}H_{32}O_4$, and glucose. (J. P. C., 4e sér., i. 236.) Turpeth root is purgative, somewhat less powerful than jalap, and rather slow in its action. From one to three drachms (3.9–11.6 Gm.) may be given in decoction and from fifteen grains to a drachm (1–3.9 Gm.) in powder. (Mèrat and De Lens.) Andouard (Ann. Thér., 1866) states that the resin of turpeth is an active purge in doses of seven or eight grains (0.45–0.5 Gm.).

Tussilago. *Tussilago Farfara*, L. Coltsfoot. *Folia Farfara*, P. G. *Tussilage*, Pas d'âne, Fr. *Huftattig*, Rosshuf, G. (Fam. Compositæ.)—Coltsfoot is a perennial herb, with a creeping root, which early in the spring sends up several leafless, erect, simple, unifloral scapes or flower-stems, five or six inches high and bearing appressed scale-like bracts of a brownish-pink color. The flower, which stands singly at the end of the scape, is large, yellow, compound, with hermaphrodite florets in the disk, and pistillate, fertile florets in the ray. The latter are numerous, linear, and twice the length of the former. The leaves do not make their appearance until after the flowers. They are radical, petiolate, large, cordate, angular, toothed at the margin, bright green upon their upper surface, white and downy beneath. The plant grows spontaneously both in Europe and North America. In this country it is found upon the banks of streams from Nova Scotia and New Brunswick south to New York and west to Minnesota. It flowers in April and June. The whole of it is employed, but the leaves most so. They should be gathered after their full expansion, but before they have attained their greatest magnitude. The flowers have an agreeable odor, which they retain after desiccation. The dried root and leaves are inodorous, but have a rough, bitterish, mucilaginous taste. Boiling water extracts their virtues. C. S. Bondurant (A. J. P., 1887, 340) examined coltsfoot chemically. He found evidences of a bitter glucoside. Coltsfoot exercises little sensible influence upon the human system. It is, however, demulcent, and is sometimes used in chronic coughs, consumption, and other affections of the lungs. The expectorant properties which it was formerly thought to possess are not obvious. The leaves were smoked by the ancients in pulmonary complaints, and in Germany they are said to be substituted for tobacco. Cullen used the fresh juice in *scrofula*, several ounces daily. The decoction made by boiling one troyounce in one pint of water is commonly given in teacupful doses.

Tussol. *Antipyrine Mandelate* (Phenyl-glycolate). $C_{11}H_{12}N_2O_5.C_6H_5CH(OH)COOH$.—It forms a white powder, fusing at 52° to 53° C. (125.6° – 127.4° F.), is soluble in water, and is recommended in the treatment of whooping cough in the following doses: for children under one year, from three-fourths to one and a half grains (0.048–0.096 Gm.); from two to four years, four to six grains (0.26–0.4 Gm.).

Tutty. *Tutia. Impure Oxide of Zinc.*—This oxide is formed during the smelting of lead ores containing zinc. It is deposited in the chimneys of the furnaces, in the form of incrustations, moderately hard and heavy, and studded over with small protuberances of a brownish color on the outside and yellowish within. As it occurs in commerce, the pieces occasionally present a bluish cast, from the presence of small particles of metallic zinc. Sometimes a spurious substance is sold for tutty, consisting of a mixture of blue clay and copper filings, made into a paste with water and dried on an iron rod. It is distinguished from the genuine tutty by its diffusing in water and exhaling an earthy odor, and by its greater friability. Tutty is used solely as an external desiccant. To fit it for medicinal use it must be reduced to fine powder, which is dusted over the affected part, or applied in the form of an ointment.

Tylophora Leaves. *Tylophora Folia. Br. Add.* (Fam. Asclepiadaceæ).—The dried leaves of *Tylophora asthmatica* (L.), Wight and Arnott. (*Tylophora fasciculata*, Ham.), are used in certain parts of India as a poison for vermin, and have been used with fatal results as a poison. *Tylophora asthmatica*, which grows in Bengal, Burmah, and Ceylon, has been known in Indian medicine since 1780, and has been largely used in both the civil and the military medical service of Madras. It is officially described as "petiolate, entire, from two to five inches (five to twelve and a half centimetres) long and from three-quarters of an inch to two and one-half inches (eighteen to sixty-five millimetres) broad, lanceolate-ovate or ovate or subrotund in outline, somewhat cordate at the base, abruptly acuminate; rather leathery in texture, glabrous on the upper surface, and finely downy on the lower; of a brownish-green color, which is paler on the lower surface. Odor slightly aromatic; almost devoid of taste." *Br. Add.*

David Hooper has separated from this drug an alkaloid, *tylophorine*, soluble in ether and alcohol, but scarcely so in water; forming crystalline salts, and striking with nitric acid a purplish red color, with Fröhde's reagents a deep sap-green, and with potassium dichromate and sulphuric acid a dirty violet. *Tylophora* resembles in its activity ipecac, and is used as a substitute for that drug in bronchitis and in dysentery. In doses of from 20 to 30 grains (1.3–2.0 Gm.) it is used as an emetic. The expectorant dose is from one-half to two grains (0.032–0.13 Gm.).

Ulex. *Ulex europæus*, L. (Fam. Leguminosæ), is the common furze, gorse, or whin so conspicuous in the waste places and by the roadsides of Great Britain, from its spiny branches and bright yellow flowers situated on the spines, either solitary or in pairs. In the seeds of this plant, A. W. Gerrard has found an alkaloid, *ulexine*. In 1890 Kobert (*D. M. W.*, 1890), as the result of an elaborate physiological study, came to the conclusion that ulexine and cytosine are identical. The suggestion has given rise to a considerable chemico-physiological discussion, a brief abstract of which may be found in *P. J.*, Feb. 1891. Kobert found indications of a second alkaloid in ulex. Partheil (*A. Pharm.*, 1892, 448; 1894, 486) and Plugge (*A. Pharm.*, 1894, 444) are in accord as to the identity of ulexine and cytosine. Ulexine has been used in cardiac dropsy. Dose, from one-fifteenth to one-twentieth of a grain (0.004–0.003 Gm.).

Ulmaren is the name given by Bourcet to a mixture of the salicylic acid esters of the higher aliphatic alcohols. It has been stated to contain 75 per cent. of salicylic acid. Ulmaren is described as a heavy, pale yellowish-red, refractive, neutral, or weakly acid liquid, of pleasant, faint odor recalling salol, and burning taste. Its sp. gr. at 15° C. (59° F.) is 1.06; and its boiling point lies between 237° C. and 242° C. (458.6°–467.6° F.). It crystallizes from an equal volume of petroleum benzin, and is almost insoluble in water, but is soluble in alcohol, ether, and chloroform. Animal experimentation (*Th. M.*, 1903, xvii.) showed that in moderate doses it is well taken, but if given in large doses by the mouth causes in the dog vomiting and purging, and in the rabbit a dose of 0.07 Gm. per kilogramme intraperitoneally injected, caused death from asphyxia. It is recommended to be used as an external application in rheumatic and neuralgic diseases, as well as in gout, either to be painted on the part and covered with waxed paper or used in the form of an ointment made up with lanolin, in which case it should be present in the proportion of 30 per cent. After epidermatic application the salicylic acid reaction may be demonstrated in the urine in three hours and lasts for three days. It is affirmed to have marked analgesic, antipyretic and antirheumatic powers (*B. G. T.*, June, 1903). Dose, fifteen to forty-five grains (1–3 Gm.); externally thirty to sixty grains (2–3.9 Gm.).

Ultramarine. *Outremer, Fr. Ultramarin, G.* This fine blue pigment was formerly obtained from lapis lazuli, or lazulite, a mineral of Siberia. It is now prepared artificially on a very large scale. In preparing it, a mixture of soft clay with sodium sulphate, charcoal, caustic soda, and sulphur is heated in crucibles. In this way a colorless compound is first produced, termed white ultramarine. This, however, soon becomes of a green color. The green ultramarine thus obtained, which is also used as a color, is then mixed with sulphur and heated. The sulphur takes fire and is allowed to burn in the air, when the product becomes of a fine blue color. (*Roscoe and Schorlemmer*, vol. ii, 459.) It is thought to be a compound of aluminum and sodium silicates with sodium polysulphide, although the sulphur present is retained in two conditions, part being deposited when ultramarine is treated with acids and part escaping as hydrogen sulphide.

Umbellularia. *Umbellularia californica* (Arn.), Nutt. *California Laurel. Spice Tree.* (Fam. Lauraceæ).—The leaves of this California tree are employed in neuralgic headaches, and in intestinal colic and atonic diarrhoea; also externally as a mild counter-irritant. Stillman and O'Neill (*N. R.*, 1883) obtained from the seeds a new acid, *umbellulic acid*. The leaves are said also to contain about 4 per cent. of a volatile oil, having a specific gravity of 0.936, a warm camphoraceous taste, and a strong pungent odor. Burse has separated from the oil by fractional distillation *umbellol*, an oil having the formula $C_{26}H_{42}O$, which dissolves in concentrated sulphuric acid with red color, and is narcotic (*Ap. Ztg.*, xi.). According to Schimmel & Co. (*Schim. Rep.*, April, 1897), it also contained cineol, $C_{10}H_{18}O$. It is probable that the volatile oil is a strong local anæsthetic, as it has been found to act rapidly when brought in contact with exposed pulp or sensitive dentine. The fluidextract has been used in doses of from ten to thirty minims (0.6–1.8 Cc.).

Umbur. *Terra Umbra*.—A mineral of a fine compact texture, light, dry to the touch, shining when rubbed by the nail, and of a fine pale brown color, which changes to a peculiar beautiful deep brown by heat. According to Klaproth, it contains 13 parts of silica, 5 of alumina, 48 of ferric oxide, 20 of manganese, and 14 of water in 100. *Burnt umbur*, as well as the mineral in its unaltered state, is used in painting. The umbur of commerce is said to be brought chiefly from the island of Cyprus.

Uranium.—Atomic weight, 236.7. The salts of the metal uranium are violent poisons, producing not only severe gastro-enteritis and nephritis, but also acting specifically on the hæmoglobin of the blood, affecting its oxygenating powers. (See P. J., Sept. 1890.) They have been carefully investigated by Jacob Woroschilsky (*Arbeiten d. Pharm. Inst.*, Dorpat, v. 1890), who finds that they are violent poisons, though acting slowly, especially when given subcutaneously, small toxic doses producing death almost as rapidly as larger ones. In the lower animals, 1 milligramme of the oxide per kilogramme will produce an intense parenchymatous nephritis, followed by violent inflammation of the intestines. There is marked elevation of the blood pressure and widespread degeneration of the tissues, especially of the blood vessels. In mild cases of poisoning a transient glycosuria is a primary symptom. The uranium nitrate has been affirmed by West to be useful in *diabetes mellitus* (Kronpetzky prefers the acetate), in doses of one to two grains (0.065–0.13 Gm.), three times a day, increased to twenty grains (1.3 Gm.) a day. They have been used on the principle of *similia similibus curantur* in renal diseases. Augermayer affirms that the salts of uranium are highly toxic, half a milligramme per kilogramme of body weight being sufficient to cause death. (Ph. J., Oct. 30, 1897, 378.)

Urasol. Acetyl-methylene-disalicylic Acid.

$\text{CH}_2(\text{C}_6\text{H}_5-\frac{\text{OC}_2\text{H}_3\text{O}}{\text{COOH}})_2$. This substance, introduced into medicine by S. Lewis Summers, is said to be formed from about 75 per cent. of salicylic acid, 16 per cent. of acetic acid, and 8 per cent. of formaldehyde. It occurs as a yellowish-white powder, insoluble in water, soluble in ether and alcohol. It has been used in doses of five to eight grains (0.32–0.5 Gm.), given in capsules, in *muscular rheumatism*, *irregular gout*, and as a germicide in *cystitis* and other inflammations of the genito-urinary tract.

Urea. $\text{CO}(\text{NH}_2)_2$. *Carbamide*. *Urée*, Fr. *Harnstoff*, G.—For an account of the physical and chemical properties of urea, the reader is referred to treatises upon physiology. Urea has been employed in practical medicine as a hydragogue diuretic in the treatment of *dropsies* and as a tonic alterative in *phthisis* (*L. L.*, December, 1901). Dose, ten grains (0.65 Gm.) every six hours; increase *pro re nata*.

Thio-urea is a substance in which one atom of oxygen in a molecule of urea is replaced by an atom of sulphur, $\text{CS}-\frac{\text{NH}_2}{\text{NH}_2}$. According to Paul Binet (*Rev. Méd. de la Suisse Rom.*, 1893), it is a very active poison, paralyzing the nerve centres, but leaving intact the peripheral nerves and the muscles.

Urechites. *Urechites suberecta*, Jacq. *Savannah Flower*. *Yellow-flowered Nightshade*.—This is an apocynaceous plant, which grows abundantly in the West Indian Islands, and is said to be used in

Jamaica by the negroes as a poison. The symptoms which it produces are violent vomiting and purging, with convulsions. J. J. Bowrey (*J. Chem. S.*, June, 1878) has isolated from it two glucosides, *urechitin* and *urechitoxin*, having respectively the formula $\text{C}_{28}\text{H}_{42}\text{O}_8$ and $\text{C}_{13}\text{H}_{20}\text{O}_5$. Isaac Ott (*T. G.*, 1880) finds the plant to be a powerful cardiac poison, first increasing and then depressing the arterial pressure, and finally, if the dose be large enough, killing by producing cardiac arrest. The results reached by Ott are in accord with those of Ralph Stockman (*Laborat. Rep.*, *Royal College of Physicians*, Edinburgh, vol. iv., 1892), who finds that both of the glucosides are very active poisons belonging to the digitalis group. On the other hand, Vowinkie came to the conclusion that even small doses of the plant depress the heart, and experiments made upon man by Bowrey show that in large doses the drug produces nausea, vomiting, general depression, great perspiration, and slight slowing of the pulse. Stockman (*Rev. de Clin. et de Thé.*, June 29, 1892) found that the leaves contain a toxic alkaloid, which he calls *urechitine*, $\text{C}_{28}\text{H}_{42}\text{O}_8 + \text{H}_2\text{O}$, and a glucoside, *urechitonin*, which is less toxic. In Jamaica the drug is said to have been used in the treatment of *intermittent* and other *sthenic fevers*. The dose of the fluidextract is from two to ten minims (0.12–0.6 Cc.).

Urginea. *Br. Add.* *Indian Squill*.—The younger bulbs of *Urginea indica*, Kunth, also the younger bulbs of *Scilla indica*, Baker (*Ledebouria hyacinthina*, Roth), taken soon after the plant has flowered. "The bulbs of *Urginea indica* are tunicated, consisting of fleshy coats which enclose each other completely; in size varying as much as the common onion; color whitish; taste bitter and acrid. The bulbs of *Scilla indica* are not tunicated like an onion, but made up of thick fleshy imbricated scales; otherwise, except that they are somewhat smaller, they resemble those of *Urginea indica*." *Br. Add.*

The bulbs of Indian squill have long been used in India for purposes similar to that for which the official squill is employed in Europe and America, but no sufficient chemical examinations have been made to prove the identity of the Indian and European drugs. The *Br. Add.* recognizes a *vinegar* (*Acetum Urgineæ*, *Br. Add.*, two and a half ounces to the pint), dose, ten to thirty minims (0.6–1.8 Cc.); an *oxymel* (*Oxymel Urgineæ*, *Br. Add.*), dose, one-half to one fluidrachm (1.8–3.75 Cc.); a *pill* of ipecacuanha with *urginea* (*Pilula Ipecacuanhæ cum Urgineæ*, *Br. Add.*); a *compound pill* (*Pilula Urgineæ Composita*, *Br. Add.*); a *symp* (*Syrupus Urgineæ*, *Br. Add.*), dose, one-half to one fluidrachm (1.8–3.75 Cc.), and a *tincture* (*Tinctura Urgineæ*, *Br. Add.*, four ounces to the pint), dose, five to fifteen minims (0.3–0.9 Cc.).

Uricedin.—Prepared by clarifying lemon juice, and adding for every fifty parts of citric acid in it, twenty parts of sulphuric acid; four parts of 25 per cent. hydrochloric acid, and sufficient sodium carbonate to nearly neutralize the acids. One part of lithium carbonate, neutralized with lemon juice, is then added, and the whole evaporated and granulated. It contains sodium sulphate, chloride, and citrate, with lithium citrate. Used in *gout* and *rheumatism*.

Urisolvin.—A compound of pure urea and acid lithium citrate used as a diuretic and uric acid solvent, in doses of three grains (0.2 Gm.), in the form of tablets.

Urobiline. $C_{42}H_{40}N_4O_7$.—This biliary pigment, prepared from urine, occurs as a brown resinous mass soluble in alcohol, ether, chloroform, and alkaline solution. It has been proposed by Th. Roman and G. Delluc as a reagent for zinc. A few drops of a solution of urobiline in chloroform, 2 Cc. of which are mixed with 5 Cc. of absolute alcohol, will make with an alkalized solution containing zinc a green fluorescence.

Uroperin. *Lithium-diuretin.* *Theobromine-lithium-salicylate.* $C_7H_7N_4O_2Li + C_6H_4(OH)COOLi$. A compound analogous to diuretin, lithium being substituted for sodium. Used as a diuretic in doses of fifteen grains (1.0 Gm.). E. Merek has also introduced the benzoate under a corresponding name, uroperin-benzoate.

Ursal.—A compound of urea and salicylic acid, used as a substitute for sodium salicylate.

Urtica. *Urtica brálante*, Fr. *Brennessel*, G. Various species of this genus are furnished with poisonous stinging hairs. *Urtica gigas* of Australia is said frequently to kill horses, and to produce in man a sting whose impression lasts for months. (*N. R.*, 1875.) It has generally been thought that the virulence of the hairs is due to the presence of free formic acid (*A. J. P.*, xxii.), and David Hooper (*P. J.*, April, 1887) has demonstrated the presence of formic acid, or a substance very closely allied to it, in the hairs of the *Nilgri nettle* (*Girardinia palmata*). Nevertheless, it does not seem probable that formic acid is the poison. G. Haberlandt believes it to be a non-volatile albuminoid, and L. Reuter has obtained from several nettles a glucoside. (*A. J. P.*, Jan. 1890.) Oddi and Lomonaco (*Rif. Med.*, April, 1892) isolated from the common nettle a crystalline alkaloid, and found that in mammals the extract acts powerfully upon the vasomotor system, and in frogs causes centric paralysis with diastolic cardiac arrest.

U. dioica, L., or common nettle, and *U. urens*, L., or dwarf nettle, of America and Europe, have been used in medicine as local irritants, as diuretics (*A. J. P.*, 1866), and especially for the purpose of arresting uterine hemorrhage. The fluidextract may be given in doses of half a fluidrachm (1.8 Cc.) or a decoction of the strength of an ounce to a pint in teacupful doses.

Ustilago. *U. S.* 1880. *Corn Smut*.—The genus *Ustilago* belongs to the *Ustilaginaceæ*, all the members of which generally develop their spores in the ovary or anthers of the host plant, forming a slimy mass, which in maturing becomes a black dust made up of spores. They produce the *smut* in cereals. *Ustilago maydis* (DC.), Tul., is produced on the stems, the pistils (corn grains), and the male inflorescence (tassel) of the Indian corn. It is specifically characterized by its minute spherical spores, having their surface covered with echinulate warts. It is abundant in the United States. Upon the corn the smut appears in masses, varying in size from a cherry to a child's head. These masses are smooth, irregularly globose, or sometimes lobulated, having at first a livid, bluish tint, and then becoming blackish, and finally bursting and emitting the black contents, consisting of innumerable globose very minute spores, each of which is covered with beautiful little pointed processes. In a dried state the masses are blackish and covered with a black powder.

C. H. Cressler found in *ustilago* an alleged alkaloid, *secalinaline* (trimethylamine, see *Ergota*, p. 447), besides a thick, viscid, fixed oil and a

resin soluble in ether but not in alcohol. (*A. J. P.*, 1861, 306.) Rademaker and Fischer (*Nat. Drug.*, 1887, 296) believed that they had discovered a white, bitter alkaloid, *ustilagine*, soluble in ether, while H. B. Parsons decided that the fixed oil contained an acid which he provisionally named *sclerotic acid*; also an amine-like volatile substance extracted by ether. (*N. E.*, March, 1882; also *West. Drug.*, 1894.) A. W. Balch (*Journ. Boston Soc. Med. Sci.*, March, 1901) was not able to find any active substance in the smut.

The belief that corn smut is an abortifacient to the lower animals (*A. J. P.*, Sept. 1861) appears to be without foundation, as in the experiments made by the United States Department of Agriculture in 1898 (*Farmers' Bulletin*, No. 69) no effect was produced by corn smut given to pregnant cows. The experiments of James Mitchell (*T. G.*, ii, 223) that *ustilago* abolishes sensation, reflex action, and later general motor power in the frog, is contradicted by the results of Balch, who also found that enormous doses of the substance have no effect upon the color of the cock's comb. In doses of one to two drachms (3.9–7.7 Gm.) it has been claimed by W. A. N. Dorland that the fluidextract markedly increases the severity and frequency of the uterine pains in human labor. The whole drift of our present evidence is to show that *ustilago* is probably inert, and it does not seem to be a remedy of any practical value.

Vaccinium. *Vaccinium crassifolium*, Andr. (Fam. *Vacciniaceæ*).—The leaves of this American shrub are said to be astringent and diuretic, and capable of replacing *uva ursi*. Dose, of the fluidextract, from a half to one fluidrachm (1.8–3.75 Cc.).

Valeric Acid. *Valerianic Acid.* *Acidum Valericum.* *Acidum Valerianicum.* C_4H_9COOH . Mol. wt., 101.31. *Acide valériannique*, *Acide valérique*, Fr. *Valeriansaure*, *Baldriansaure*, G. *Acido valerianico*, It., Sp.

In the 1860 U. S. revision this acid was transferred from the Preparations to the *Materia Medica* list; in that of 1880 it was dropped entirely. Valeric Acid is "a colorless liquid, of an oily consistence, a penetrating, disagreeable odor, and caustic taste; and of the sp. gr. 0.935." *U. S.* 1870.

"Take of Valerianate of Soda, in coarse powder, eight troyounces; Sulphuric Acid, Water, each, a sufficient quantity. To the Valerianate of Soda add, first, three fluidounces of Water, and then three troyounces and a half of Sulphuric Acid. Mix them thoroughly, and from the mixture, after standing, separate the oily acid liquid which rises to the surface. Agitate this repeatedly with small portions of Sulphuric Acid until its specific gravity is reduced below 0.950. Then introduce it into a retort, and distil nearly to dryness, rejecting the distillate so long as it has a specific gravity above 0.940, and keeping the remainder for use. The rejected portion of the distillate, after agitation with Sulphuric Acid, may be returned to the retort during the progress of the distillation." *U. S.* 1870.

The object of this process is merely to procure valeric acid in a state adapted for the preparation of ammonium valerate. The sulphuric acid, uniting with the sodium of the sodium valerate, separates the valeric acid, which rises to the surface with the appearance of an oil. In this state it is still mixed with water, and, as the pure acid is wanted, the direction is given to agitate it with sulphuric acid, which deprives it

of the excess of water. It is now distilled in order to separate any sulphuric acid and water that may be mixed with it. Musgiller of Brooklyn, N. Y., stated that the acid cannot be obtained by the process of 1860 of a sp. gr. as low as 0.933 with ordinary sulphuric acid, and suggested that 0.935 be adopted as the official standard, as acid of this strength is equally well adapted for the preparation of the valerates, for which alone it is used. This suggestion, as to the sp. gr., was adopted at the revision of the U. S. Pharmacopœia of 1870. Musgiller proposed some modifications of the process which appear to be judicious. (See *A. J. P.*, 1869, 83; also *Proc. A. Ph. A.*, 1868.)

For modes of preparing valeric acid from the oil and roots of valerian, the reader is referred to the article on Valerian in this work. It is prepared also from amyl alcohol by reaction with a mixture of potassium dichromate and sulphuric acid, as the first step in the preparation of sodium valerate.

Valeric acid (originally valerianic acid) received its name from having been found in the oil distilled from the root of *Valeriana officinalis*, L. (Fam. Valerianaceæ). It was first obtained in 1817 by Chevreul from the oil of the dolphin, and received the name of *delphinic acid*, which, however, upon the discovery of its identity with the acid afterwards obtained by Pentz from valerian, was superseded by its present title. It has been obtained also from the bark and fruit of *Viburnum Opulus*, L., and other species of *Viburnum* (Fam. Caprifoliaceæ), the sap wood of the European elder (*Sambucus nigra*, L.) (Fam. Caprifoliaceæ), the root of *Angelica Archangelica*, L. (*Archangelica officinalis*, Hoffm.) (Fam. Umbelliferae), and from various organic products of the vegetable and animal kingdom.

Properties.—Valeric acid is a colorless liquid, of an oily consistence, a repulsive odor, resembling, however, that of valerian, and a pungent, sour, acrid, disagreeable taste. Its sp. gr. is variously given from 0.946 at 0° C. to 0.931 at 20° C. (Beilstein, *Org. Chem.*, i. 406.) As stated in the U. S. P. 1870, it is 0.935. It remains liquid at 8° below zero (F.), and boils at 174° C. (345.2° F.) (Trommsdorff.) It is soluble in thirty parts of cold water, and when agitated with water takes up about 20 per cent., without losing its oily consistence, and rises to the surface of the liquid. Alcohol and ether mix with it in all proportions. It is very soluble in strong acetic acid, and dissolves camphor and some resins. (Trommsdorff.) It forms salts with the alkalies, and reddens litmus paper strongly, but the blue color gradually returns in a warm place. Its composition is represented by $C_5H_{10}O_2$, and it is a mixture of two isomeric acids (*isovaleric acid* and optically active valeric acid). This is true as well of the valeric acid that is obtained from the *Valeriana officinalis*, L., the *Angelica Archangelica*, L., and that which results from the oxidation of the amyl alcohol of fermentation with the aid of chromic acid. The strong acid readily unites with a molecule of water to form a hydrated acid, $C_5H_{10}O_2 + H_2O$. This compound, formerly known as the *trihydrate*, has a sp. gr. 0.945, and boils at a lower temperature than the strong acid. It has a much milder taste than the pure acid, and is at the same time somewhat saccharine. The U. S. P. 1870 gave the following tests of the official acid: "A solution of Valerianic Acid, in fifty parts of hot water, saturated with hydrated carbonate of zinc, yields a liquid, which, when filtered and evaporated to ten

parts and cooled, affords white pearly crystals of valerianate of zinc. The mother-water, drained from these crystals, should not yield, by further evaporation and cooling, a salt crystallizing in six-sided tables, and very soluble in water. When the Acid is added to a concentrated solution of acetate of copper, the transparency of the solution is not disturbed." The former of the last two tests indicates the absence of acetic, the latter of butyric acid. The acid distilled from the oil or root of valerian has been employed in *nervous affections*, and possesses properties similar to those of valerian. According to Landerer, the acid artificially produced does not operate therapeutically so satisfactorily as the native product. The dose would probably be about the same as that of the oil of valerian, given in sweetened water.

Valeridin. *Valerydin. Sedatin. Iso-valeryl-p-phenetidin.* $C_6H_5 \left\{ \begin{array}{l} NHCOOC_4H_9 \\ OC_4H_9 \end{array} \right.$. This substance

occurs as white, glistening needles, which are readily soluble in alcohol or chloroform, difficultly soluble in ether, and almost insoluble in water. It is obtained by heating isovaleric acid with p-phenetidin. C. Erdmann (*Ph. Ztg.*, xliii.) commends this substance in doses of from eight to fifteen grains (0.5–1.0 Gm.) a day, as a succedaneum for valeric acid, and as being very serviceable in *migraine, neuralgia, and hysteria*.

Validol. *Menthol Valerate*, $C_{10}H_{19}O.CO.C_4H_9$. Validol is a clear, colorless liquid, of a mild, pleasant odor, and slightly bitter taste, said to contain 30 per cent. of menthol combined chemically with 70 per cent. of valeric acid. It was originally proposed by Schwersenski (*Th. M.*, 1897) as being locally non-irritant and affording a means of exhibiting menthol; for its local action in *pruritus, gastralgia, coryza*, various mucous inflammations, and as an antispasmodic in *migraine, neurasthenia, hysteria*, and other neuroses. Other clinicians have commented favorably upon the drug as an antiemetic and stomachic. It is stated to be specially eliminated through the urine, to which it imparts a peculiar odor. Dose, five to twenty minims (0.3–1.3 Cc.); locally 10 to 15 per cent. ointment is recommended.

Validolum Camphoratum is a 10 per cent. solution of camphor in validol.

Valonia. *Acorn Cups.* *Vallone, Vêlanède, Gallon, Fr. Knopperr, Walonen, G.*—The great cups of the acorns of the *Quercus agrifolia*, L. (Fam. Cupuliferae), a native of Bosnia, contain a very large percentage of tannin. They are extensively exported for dyeing and tanning, and have been employed as an astringent in *diarrhœa*.

Valyl. *Valeric Acid Diethylamide.*—*Valyl*, $C_4H_9.CO.N(C_2H_5)_2$, occurs as a colorless liquid having a characteristic odor and burning taste, and boiling at 210° C. (410° F.). According to Kionka (*D. M. W.*, xxvii. 1901), valyl produces cerebral excitement, attended with convulsions probably of cerebral origin, as there is no increased reflex activity. It is said primarily to increase the blood pressure and to have little action upon the heart or respiration. It is somewhat irritant, but may be given in four per cent. aqueous solution, and has been used as a substitute for valerian in *hysterical and allied neuroses*. Dose, four to fifteen grains (0.26–1.0 Gm.) three times a day, preferably administered with an equal amount of tallow in gelatin capsules.

Vanadic Acid. *Acidum Vanadicum. (Meta-vanadic Acid, HVO₃.)*—Forms golden-yellow scales, which are only slightly soluble. According to

Le Blond and C. David, vanadic acid is actively antiseptic, and very useful in solutions for the skin, 0.05 in 1000; for gynecological use, 0.17 in 1000. *Oxydasin* is said to be a solution, 0.5 in 1000. (B. G. T., 145.)

Sodii Metavanadas. Sodium Vanadate. NaVO_3 . This is a yellowish-white powder, freely soluble in hot water.

Ferri Vanadas. Iron vanadate.—A dark, grayish-brown powder, almost insoluble in water.

Lithii Vanadas. Lithium Vanadate. $\text{LiVO}_3 + \text{H}_2\text{O}$.—A yellowish-white crystalline powder, freely soluble in water.

In the arts vanadic acid is used in various oxidizing processes as a carrier of oxygen, effecting by its presence the more efficient action of other oxidants, as in the aniline black formation, where a small amount of ammonium vanadate is capable of taking the place of large amounts of chlorates and similar oxidizing agents. It is also used in vanadium inks.

Vanadic acid and its soluble salts have been shown (Lyons Méd., 1899) to be actively poisonous, 0.017 gramme per kilo given to the rabbit intravenously producing rapid death. When given to man in overdose they produce gastrointestinal irritation, but it is alleged that in minute dose they increase the elimination of urea, stimulate nutrition, and act favorably in *anæmia*, *chlorosis*, *chronic rheumatism*, and *tuberculosis*. The dose of the acid is given as from $\frac{1}{15}$ to $\frac{1}{4}$ grain (0.0005–0.001 Gm.); but the sodium salt is much less irritant, and therefore preferable; dose, one-sixty-fourth to one-twenty-fifth of a grain (0.001–0.0026 Gm.), administered in dilute solution three times a day. The lithium vanadate has been specially commended by some practitioners in *gout*, and the iron salt in *anæmia*. The dose of the latter is the same as that of the sodium salt.

Vanadium.—(Atomic weight, 50.8.) Vanadium has been studied physiologically in the form of the salts of *vanadic acid*, especially in the *metavanadate of sodium*. The vanadates are well known to act as carriers of oxygen in many chemical reactions. It has been affirmed that vanadic acid readily yields its oxygen and as readily receives oxygen from other substances, so that in the blood it is first converted into *hypovanadic acid* and then by the oxyhæmoglobin is changed into *hypervanadic acid*. The salts of vanadic acid are said to produce in the lower animals vomiting, profuse diarrhœa, disturbances of respiration, tonic and clonic convulsions, loss of sensibility, and cardiac depression.

Therapeutically, the vanadium compounds have been used by Laran, and by Lyonnet, Martz, and Martin. It is claimed that in proper doses they increase the appetite and have a tendency to increase weight, are antihidrotic and useful in *tuberculosis*, *chlorosis*, and other diseases. Dose, of the acid, from one-half to one milligramme (1-128th to 1-64th grain), given in solution in the course of twenty-four hours. (For literature, see Schmidt's *Jahrbücher*, Bd. 265, 229.)

Vandellia. *Vandellia diffusa*, L. (Fam. Scrophulariaceæ.)—This is an herb of Paraguay, said to be used by the natives as an emetic. (P. J., 1872, 849.)

Vasogen. *Vaselinum Oxygenatum.*—This is a feebly alkaline, yellow-brown fluid, of a peculiar but not disagreeable odor and taste, which readily emulsifies with water. It is said to be "oxygenated vaseline or petrolatum," and again that "it con-

tains about 25 per cent. of olein, saponified with anhydrous ammonia, and mixed with vaseline and vaseline oil." Vasogen serves as a vehicle for ointments whose active ingredients, it is said, are absorbed with great rapidity from the skin. There have been offered camphor vasogen, 33½ per cent.; iodine vasogen, from 3 to 10 per cent.; menthol vasogen, 2 per cent., and the list might be extended almost indefinitely. There does not seem to be any reason for supposing that the vasogen ointments are really superior to ointments made with vaseline.

Venetian Red. *Bolus Veneta.*—A dull red ochrey substance used in painting.

Verbascum. *Verbascum Thapsus*, L. *Mullein.* *Flores Verbasci*, P. G. *Bouillon blanc*, Molène, Fr. *Wollkraut*, *Königskerze*, G. (Fam. Scrophulariaceæ.)—The ordinary mullein weed is too well known to need description. As remedial agents both leaves and flowers have been employed. They have a very slight odor, and a mucilaginous, herbaceous, bitterish, feeble taste. Mullein leaves are demulcent and emollient, and are thought to possess anodyne properties, which render them useful in pectoral complaints. On the continent of Europe, an infusion of the flowers, strained in order to separate the rough hairs, is considerably used in mild *catarrhs*. An oil, produced by saturating olive oil with mullein flowers, during prolonged exposure to the sun, is used as a local application in Germany for *piles* and other *mucous membrane inflammations*. The mullein oils sold in pharmacies are of this nature, or some of them alcoholic tinctures. The dried leaves are sometimes smoked to relieve irritation of the respiratory mucous membranes; fomentations with mullein leaves also have some repute as anodynes. Internally, the decoction (an ounce to the pint, flowering tips) may be taken in the quantity of from four to six fluidounces.

According to L. Rosenthal (P. J., July, 1902), the seeds of *Verbascum sinuatum*, which are used in Greece as a fish poison, contain 6.13 per cent. of saponin. Traces of the same substance were found in the fruits of *V. phlomoides*, L., and *V. thapsiforme*, Schrad.

Verditer.—Two preparations of copper, employed as pigments, are known by this name in commerce, and are distinguished by the epithets of blue and green. *Blue verditer* is prepared in London from the solution of copper nitrate obtained in precipitating silver by copper. According to Gray, this solution is poured while hot upon whiting (calcium carbonate), and the mixture stirred every day till the liquor loses its color, when it is decanted, and fresh portions added till the proper color is obtained. By a process for procuring this pigment, invented by Pelletier, the solution of copper nitrate is decomposed by quicklime, and the precipitate, after being washed, is incorporated intimately with another portion of quicklime. By the former process, a copper carbonate is obtained; by the latter, a mixture of copper and calcium hydroxides. *Green verditer* is prepared by precipitating a solution of copper nitrate by chalk or a white marl, and consists of copper carbonate mixed with an excess of the calcareous carbonate.

Vernonia. *Vernonia anthelmintica*, Willd. (Fam. Compositæ.)—This is an East Indian plant, whose black, bitter, and nauseous seeds have a high reputation in Ceylon as an anthelmintic in doses of sixty grains (3.9 Gm.). (P. J., April, 1883; also *Ph. Rev.*, 1896, 274.)

Veronal. *Diethylmalonyl Urea. Diethyl Barbituric Acid.*

$$\begin{array}{c} \text{C}_2\text{H}_5 > \text{C} > \text{CO.NH} \\ \text{C}_2\text{H}_5 > \text{C} > \text{CO.NH} > \text{CO.} \end{array}$$

Colorless crystals with a melting point of 191° C. (375.8° F.), slightly bitter in taste, soluble in 145 parts of water at ordinary temperature and in 12 parts of boiling water. Originally introduced as an hypnotic by Fischer and von Mering, veronal has been favorably reported upon by a number of clinicians as producing a sleep which usually develops in fifteen to twenty minutes and continues for many hours, its action being more sure and more continuing than that of trional. It is affirmed to act even when there is pain, and to be well borne in cases of pulmonic and cardiac disease. In the *insomnia* of the *psychoses* it is favorably reported upon. Concerning its general physiological action we have little knowledge, but C. Trautmann (*Ther. Geg.*, 1903) affirms as the result of experimental studies that it lessens nitrogenous elimination. Various authorities claim that it leaves no after effects, but Jolly, Rosenfeld, and Würth, have noticed after its administration, malaise, headache, and giddiness, and even disturbances of speech,—chiefly when given in very large doses. Analgesic powers have been attributed to it by some clinicians and denied by others. Ordinary dose, fifteen to twenty grains (1.0–1.3 Gm.); in mild cases, four to five grains (0.26–0.32 Gm.), and when there is much excitement much larger doses are well borne. Walter Berant has given as high as one hundred and twenty grains (7.7 Gm.) in twenty-four hours.

Veronica. *Veronica officinalis*, L. Speedwell. *Véronique mâle*, Fr. Ehrenpreis, G. (Fam. Scrophulariaceæ).—Several species of *Veronica*, common to Europe and this country, have been medicinally employed. Of these, *V. officinalis*, L., and *V. Beccabunga*, L., or *brooklime*, are the most conspicuous. *V. officinalis* has a bitterish, warm, and somewhat astringent taste. Enz found in it a bitter principle soluble in water and alcohol, but scarcely so in ether, and precipitated by the salts of lead, but not by tannic acid; an acrid principle; red coloring matter; a variety of tannic acid producing a green color with ferric salts, a crystallizable fatty acid, with malic, tartaric, citric, acetic, and lactic acids; mannite; a soft, dark green, bitter resin. Mayer of New York, found evidences of an alkaloid and of a saponaceous principle. (*A. J. P.*, 1863, 209.) The plant has been considered diaphoretic, diuretic, expectorant, tonic, etc., and was formerly employed in *pectoral* and *nephritic complaints*, *hemorrhages*, *diseases of the skin*, and in the treatment of *wounds*. *V. Beccabunga* was used in the fresh state as a blood purifier and in *scurvy*.

Vicirine.—This substance is obtained from the bark of the *Remijia Vellozii*, DC. (Fam. Rubiaceæ), of Brazil. It is used in Brazil in doses of from one to four grains (0.065–0.26 Gm.) repeated *pro re nata*, as a tonic and as an antiperiodic in place of quinine.

Vienna Paste. *Potassa Cum Calce.* U. S. 1890. *Potassa with Lime.*

"Potassa, five hundred grammes [or 17 ounces av., 279 grains]; Lime, five hundred grammes [or 17 ounces av., 279 grains], to make one thousand grammes [or 35 ounces av., 120 grains]. Rub them together, in a warm iron mortar, so as to form a powder, and keep it in a well-stoppered bottle." U. S. 1890.

"A grayish-white powder, deliquescent, having a strongly alkaline reaction, and responding to

the tests for calcium and potassium. It should be soluble in diluted hydrochloric acid without leaving more than a small residue." U. S. 1890. It should not effervesce on the addition of an acid. It is prepared for use by being made up into a paste with a little alcohol. The paste is applied for ten or fifteen minutes to the part to be cauterized, exactly as with potassium hydroxide, than which escharotic it is more manageable, being slower in its operation, and less deliquescent. Filhos has improved this caustic by forming it into sticks. To prepare it thus, the potassium hydroxide is perfectly fused in an iron spoon, and one-third of its weight of quicklime is added in divided portions, the whole being stirred with an iron rod. The fused mass is then run into lead tubes, closed at one end, about three inches long, and from a quarter to half an inch in diameter in the clear. The sticks are kept, still enclosed in the lead tubes with the open end downward, in thick glass tubes, containing some powdered quicklime, and closed with a cork, between which and the stick some cotton is put to steady the caustic. When employed, as much of the caustic is uncovered at the end by scraping off the lead, as it is proposed to use.

Vinca.—Under this name are included *V. major*, L., *Greater Periwinkle*, and *V. minor*, L., *Lesser Periwinkle* (Fam. Apocynaceæ). It is said to be very useful in arresting *menorrhagic* and other *hemorrhages*. (*P. J.*, 1871, 961; *Ibid.*, 1873, 963; also *A. J. P.*, 1872.)

Vincetoxicum. *V. officinale*, Moench. *Cynanchum Vincetoxicum*, Pers. *Asclepias Vincetoxicum*, L. *White Scallow-wort. Vincetoxicum. Asclépiade, Dompé-venin, Hirundinaire, Fr. Schwalbenwurz, Giftwende*, G.—A perennial, herbaceous European plant, the root of which was formerly esteemed a counterpoison, and hence the botanical name. It has a bitterish, acrid taste, and, when fresh, a disagreeable odor, which is diminished by drying. Taken internally, especially in the recent state, it excites vomiting, and is capable, in larger quantities, of producing dangerous if not fatal inflammation of the stomach. Feneulle found in the root a principle analogous to emetin. It has been used in skin diseases and scrofula.

Vinegar. Acetum.—Vinegar is produced by the acetous fermentation in infusions of mixed malted and unmalted grain, or in various fruit juices. Any substance which is capable of undergoing the alcohol fermentation is further liable, under the influence of a microscopic plant, *Mycoderma aceti*, and exposure to the air at a temperature between 24° C. (75° F.) and 35° C. (95° F.), to undergo further change with oxidation, which converts the alcohol into acetic acid. Practically for success there should not be more than 12 per cent. of alcohol in the original fluid. The mycoderma may exist as a pellicle composed of extremely small cells (micrococci) in contiguous rows, or finally enveloped in a glue-like mass, or it may be in the form of rod-like cells (bacilli) more or less dispersed through the fluid.

In the quick German process for making vinegar a mixture of one part of 80 per cent. alcohol, four or six parts of water, and one-thousandth of honey or extract of malt, at a temperature of 24° C. (75° F.) to 35° C. (95° F.), is allowed to percolate through beech shavings, previously steeped in vinegar, and contained in a deep oaken tub, in which is a wooden diaphragm perforated with numerous small holes, loosely filled with

packthread about six inches long. It is essential to the success of the process that a current of air shall pass through the tub. In order to establish this current, eight equidistant holes are pierced near the bottom of the tub, forming a horizontal row, and four glass tubes are inserted vertically in the diaphragm, of sufficient length to project above and below it. The air enters by the holes below, and passes out by the tubes. Although the air is necessary for the furnishing of oxygen, acetification consisting chiefly in the oxidation of the alcohol, the beech shavings and similar articles chiefly aid in the process by affording surface upon which the mycoderms can grow. During the process the temperature rises to 37° C. (100° F.) or 40° C. (104° F.), and remains nearly stationary while the process is going on favorably. The liquid is drawn off by a discharge pipe near the bottom, and must be passed three or four times through the tub before the acetification is completed, which generally occupies from twenty-four to thirty-six hours. According to Wimmer, pieces of purified charcoal, about the size of a walnut, may be advantageously substituted for the beech shavings in the process.

In 1862, Pasteur substituted for the German process the sowing of the mycoderms upon the surface of a mixture of wine and vinegar, or of water, alcohol (2 per cent.), and acetic acid (1 per cent.), adding alcohol daily in small quantities after about half that contained in the original liquid had been converted into acetic acid, until a vinegar of sufficient strength was produced. The French process was improved in 1869 by Laugier, and it was subsequently further elaborated by Emanuel Wurm. (For details, see *P. J.*, xi. 133.)

In England, vinegar is made from the infusion of malt. The fermented wort is caused to fall in a shower upon a mass of fagots of birch twigs occupying the upper part of a large vat, and, after trickling down to the bottom, is pumped up repeatedly to the top, to be again allowed to fall, until the acetification is completed. This mode of oxidizing the alcohol in the fermented wort has the advantage of rendering insoluble certain glutinous and albuminous principles, which, if not removed, would cause a muddiness in the vinegar and make it liable to spoil.

In the United States, vinegar is largely made by the German method of oxidizing very diluted alcohol, and is called *spirit vinegar*; it is often prepared from cider—*cider vinegar*. The cider is placed in barrels (with their bung holes open) which are exposed during the summer to the heat of the sun. The acetification is completed in the course of about two years. The progress of the fermentation, however, must be watched, and as soon as perfect vinegar is formed, it should be racked off into clean barrels. Without this precaution, the acetous fermentation would run into the putrefactive, and the vinegar be spoiled. Cider vinegar contains no aldehyde. It contains malic acid, and therefore yields a precipitate with lead acetate. The want of such a precipitate indicates that the alleged cider vinegar is a manufactured substitute, although a fictitious article might yield a similar precipitate.

Vinegar may be clarified, without impairing its aroma, by throwing about a tumblerful of boiling milk into from fifty to sixty gallons of the liquid, and stirring the mixture. This operation also makes red vinegar pale.

The series of changes which occur during the *acetous fermentation* is called *acetification*. Dur-

ing its progress there is a disengagement of heat; the liquor absorbs oxygen and becomes turbid; filaments form, and upon the completion of the fermentation, form a pultaceous mass, leaving a clear liquor containing the acetic acid. The explanation of Liebig is that the alcohol loses two atoms of hydrogen as the first effect of oxidation, and becomes aldehyde, and this, by the absorption of one atom of oxygen, becomes acetic acid ($C_2H_3O.OH$). Thus the conversion of alcohol into acetic acid consists in, first, the removal of two atoms of hydrogen, and afterwards the addition of one atom of oxygen. The following equations represent this change:

Aldehyde is a colorless, inflammable, ethereal liquid, having a pungent taste and odor. Its density is 0.79. It absorbs oxygen gradually, and is thus converted into acetic acid, as just stated. Its property of absorbing oxygen gives it a reducing power like that possessed by glucose. Hence it responds to Fehling's test for that substance (PART III). It is characterized by its forming a crystalline compound with ammonia, and also with alkaline bisulphites; it is polymerized by the action of acids and some other reagents, and thus yields *paraldehyde* ($C_6H_{12}O_3$), a liquid boiling at 124° C. (255° F.). The name aldehyde alludes to its relation to alcohol, *alcohol dehydrogenated*. Its aqueous solution is decomposed by potassium hydroxide with formation of *aldehyde resin*. This is a soft, light brown mass, which, heated to 100° C. (212° F.), gives off a nauseous soapy odor.

Properties.—Vinegar, when good, is of an agreeable, penetrating odor, and a pleasant acid taste. According to Magnes-Lahens, wine vinegar always contains a little aldehyde. The better sorts of vinegar have a grateful aroma, probably due to the presence of an ethereal substance, perhaps acetic ether. The color of vinegar varies from pale yellow to deep red. When long kept, especially if exposed to the air, it becomes ropy, acquires an unpleasant odor, putrefies, and loses its acidity.

The essential ingredients of vinegar are acetic acid and water; but, besides these, it contains various other substances, derived from the particular vinous liquor from which it may have been prepared. Among these may be mentioned coloring matter, gum, starch, gluten, sugar, a little alcohol, and frequently malic and tartaric acids, with a minute proportion of alkaline and earthy salts. Vinegar should be devoid of lead and copper and of free sulphuric acid, as shown by its not being discolored by hydrogen sulphide, and yielding no precipitate when boiled with a solution of calcium chloride, and of such a strength that a fluidounce would require, for neutralization, not less than thirty-five grains of potassium bicarbonate. After neutralization it should be free from acrid taste, indicating the absence of acrid substances, the taste of which may have been concealed by that of the acetic acid.

MALT VINEGAR (*Acetum Britannicum*) has a brown color, and a sp. gr. from 1.006 to 1.019. The strongest kind, called *proof vinegar*, contains from 4.6 to 5 per cent. of acetic acid. That of British manufacture usually contains sulphuric acid, which the manufacturer is allowed by law to add in a proportion not exceeding one part in a thousand; but if the vinegar be properly made it does not require to be thus protected.

Vinegar is "a liquid of a brown color and peculiar odor. Specific gravity 1.017 to 1.019. 445.4 grains by weight (1 fluidounce) of it require about 402 grain-measures of the volumetric solution of soda for their neutralization, corresponding to 5.41 per cent. of real acetic acid, $\text{HC}_2\text{H}_3\text{O}_2$. If ten minims of solution of chloride of barium be added to a fluidounce of the vinegar, and the precipitate, if any, be separated by filtration, a further addition of the test should give no precipitate. Sulphuretted hydrogen causes no change of color." Br. 1885.

WINE VINEGAR (*Acetum Gallicum*) is nearly one-sixth stronger than pure malt vinegar. It is of two sorts, the white and the red, according as it has been prepared from white or from red wine. *White wine vinegar* is usually preferred. *Red wine vinegar* may be deprived of its color, and rendered limpid, by being passed through animal charcoal.

DISTILLED VINEGAR (*Acetum Destillatum*; *Vin-aigre distillé*, *Oxéolat simple*, Fr.; *Destillirter Essig*, G.) was official in the U. S. Pharmacopœia 1870, and was prepared by obtaining seven pints of distillate from eight pints of vinegar placed in a glass retort, the one pint left in the retort retaining the fixed impurities, salts, etc. One hundred grains should saturate not less than seven and six-tenths grains of potassium bicarbonate. It should be wholly volatilizable by heat, yield no precipitate with lead acetate or silver nitrate, nor change color upon the addition of hydrogen sulphide or ammonia. If silver be digested with it and hydrochloric acid afterwards added, no precipitate should be produced.

Adulterations.—The principal foreign substances which vinegar is liable to contain are sulphuric and sulphurous acids, certain acrid substances, and copper and lead, derived from improper vessels used in its manufacture. Tin has been found in it after standing a short time in tin vessels. Hydrochloric and nitric acids are but rarely present.

Barium chloride is not a suitable test for the presence of free sulphuric acid, as it will cause a precipitate with sulphates, which are often found in vinegar when no free sulphuric acid is present. The evaporation of a sample of vinegar in contact with a piece of white sugar or on white paper will often show the presence of free sulphuric acid by the charring which ensues. A very simple method, discovered by A. Ashby, of detecting free mineral acids in vinegar is mentioned by Allen (*Com. Org. Anal.*, 2d ed., i. 392). A solution of logwood is prepared from boiling water and fresh logwood chips. Separate drops of this solution are spotted on the surface of a flat porcelain dish and evaporated to dryness over a water bath. To each spot a drop of the suspected sample (concentrated first if desirable) is added, and the heating continued until it has evaporated. If the vinegar be pure the residue will be found to have a bright yellow color, but in the presence of a very small proportion of mineral acid the residue assumes a red color. The acrid substances usually introduced into vinegar are red pepper, long pepper, pellitory, grains of paradise, and mustard seed. These may be detected by evaporating the vinegar to an extract, which will have an acrid, biting taste, if any one of these substances be present. By far the most dangerous impurities in vinegar are copper and lead. The former may be detected by a brownish precipitate on the addition of potassium ferrocyanide to the concentrated

vinegar; the latter, by a blackish precipitate with hydrogen sulphide, and a yellow one with potassium iodide. Pure vinegar is not discolored by hydrogen sulphide. According to Chevallier, wine vinegar which has been strengthened with acetic acid from wood sometimes contains a minute proportion of arsenic, which is probably derived from arseniferous sulphuric acid, employed in preparing the acetic acid. (For an examination of samples of commercial vinegar by F. G. Ryan, see *A. J. P.*, 1899, p. 71.)

Vinegar has feeble antiscorbutic properties, but is at present used as a medicine only for its local astringent properties, and in the form of an enema diluted with three times its bulk of water to kill *seat worms*. In the *dermatitis* produced by exposure to the sun, made into a paste with glycerin, bismuth, and starch, it is very effective. In *hamatemesis* one ounce to a tumbler of water often acts very advantageously, and may be taken freely. At one time vinegar was largely used in pharmacy as a menstruum, but on account of its tendency to undergo decomposition it has been replaced by diluted acetic acid in both the American and British Pharmacopœias.

Vioform. $\text{C}_6\text{H}_4\text{ICl}(\text{OH})\text{N}$.—*Iodochloroquinoline* was introduced as a substitute for iodoform in surgery. According to the researches of E. Tavel, it is less toxic than iodoform, especially when brought in local contact with wounds, and is also more actively germicidal than is iodoform. Locally it is not at all irritant. (See *S. Jb.*, Bd. 267, p. 133; Bd. 272, p. 163.)

Viola. *Violet*.—The genus *Viola* (Fam. Violaceæ) includes numerous species, many, perhaps all of which are possessed of analogous medicinal properties. *Viola tricolor*, L., the *Heart's-ease*, *Pansy*, or *Johnny-jump-up* of the gardens, was formerly recognized by the U. S. Pharmacopœia; while *V. odorata*, L., and *V. pedata*, L., have held places in both the British and the United States Pharmacopœias.

V. odorata, L. (*Violette*, *Violette odorante*, Fr.; *Wohlbriehendes Veilchen*, *Veilchen*, G.; *Violetta*, It.; *Violeta*, Sp.), the common violet of Europe, resembles very closely the American blue violet, *V. cucullata*, Ait., from which, however, it is at once distinguished by its delicious fragrance. It is the *sweet blue violet* of our gardens. *V. pedata*, L., is an indigenous stemless violet, characterized by its large blue or variegated beardless flowers, and its deeply three to five-divided, pointed pedate leaves.

The flowers of *V. odorata* yield their odor and their slightly bitter taste to boiling water. Their infusion affords a very delicate test for acids and alkalies, being reddened by the former and rendered green by the latter. Their odor is destroyed by desiccation, and the degree to which they retain their fine color depends upon the care used in collecting and drying them. They should be gathered before being fully blown, deprived of their calyx, and rapidly dried, either in a heated room or by exposing them to a current of very dry air. The flowers of other species are often mingled with them, and, if of the same color, are equally useful as a chemical test.

In the root, leaves, flowers, and seeds of *Viola odorata*, Boullay discovered an alkaloid, *violine*, allied to emetine, but possessing distinct properties. It is white, soluble in alcohol, scarcely soluble in water, and forms salts with the acids. It exists in the plant combined with malic acid. Orfila asserts that it is exceedingly active and even

poisonous. It is probably found in other species of *Viola*. Mandelin (*Jahresb.*, 1883) obtained a glucoside analogous to quercitrin, which he names *viola-quercitrin*. It crystallizes out of hot water in fine yellow needles. When boiled with diluted acids, it is decomposed into *quercetin*, *isodulcite* and a fermentable glucose,

he also obtained salicylic acid from several species of *Viola*. (*A. J. P.*, 1882, 10.)

The herbaceous parts of various species of violets are mucilaginous, emollient, and slightly laxative, and have been used in *pectoral*, *nephritic*, and *cutaneous diseases*. In Europe a syrup prepared from the fresh flowers of *Viola odorata* is employed as an addition to demulcent drinks, and as a laxative for infants. The root, which has a bitter, nauseous, slightly acrid taste, acts in the *dose* of from thirty grains to a drachm (2.0–3.9 Gm.) as an emetic and cathartic. It is probable that the same property is possessed by the roots of all the violets, as it is known to be by several species of *Ionidium*, which belongs to the same family. The existence in small proportion of the emetic principle in the leaves and flowers accounts for their expectorant properties.

Virginia Creeper. *Parthenocissus quinquefolia* (L.), Planch. *Ampelopsis quinquefolia*, Michx. (*Vitis quinquefolia*, Lam., also *V. hederacea*, Willd.) *American Ivy*. *Vigne vierge*, Fr. *Wilder Wein*, *Amerikanischer Epheu*, G.—The bark twigs of this indigenous woody creeper of the fam. Vitaceæ have been used by the eclectics as an alterative, tonic, and expectorant. They contain tartaric acid and potassium and calcium tartrates, albumen, sugar, pyrocatechin, and some other principles. McCall employed the bark collected late in the fall in *dropsy*, with asserted very good results. (*Penins. and Independ. Med. Journ.*, June, 1858.) In two cases of poisoning reported by Bernays, the symptoms were violent vomiting and purging, collapse, and deep sleep, with dilated pupils. (*P. J.*, vii.)

Viscum. *Viscum album*, L. *Mistletoe*. *Gui de Chêne*, Gillon, Fr. *Mistel*, G. (Fam. Loranthaceæ.) A European evergreen parasitic shrub, growing on various trees, particularly the apple and other fruit trees, and forming a pendent bush from two to five feet in diameter. The plant is famous in the history of Druidical superstition. In the religious rites of the Druids, the mistletoe of the oak was employed, and hence was afterwards preferred when the plant came to be used as a remedy; but it is in fact identical in all respects with those which grow upon other trees. (*P. J.*, 1897, 289.) The fresh bark and leaves have a peculiar, disagreeable odor, and a nauseous, sweetish, slightly acrid and bitterish taste. *Viscin*, which forms the glutinous constituent in the berries, leaves, and stalks of the mistletoe, is the principal constituent of *birdlime*. Crude viscin may be obtained by kneading the finely bruised mistletoe bark with water, as long as anything is dissolved, and removing the ligneous impurities mechanically. A purer product may be obtained by boiling the crude product in strong alcohol, macerating the residue with ether, evaporating the ethereal extracts, purifying these extracts by kneading first with alcohol and then with water. The formula $C_{20}H_{40}O_8$ ($C_{20}H_{32} + 8H_2O$) has been given to it by Reinsch. Pawlevsky (*Bull. Soc. Chim.* (2), 34, 348) obtained from mistletoe a crystallizable acid, slightly soluble in water, in-

soluble in alcohol and ether, fusing at from 101° to 103° C. (213.8°–217.4° F.), to which he gave the formula $CH_3O_3.OH$. The berries, which are white, and about the size of a pea, abound in the peculiar viscid principle, and are sometimes used in the preparation of birdlime, of which this principle is the basis. Mistletoe is said to be productive of vomiting and purging when largely taken. The berries caused in a child three years old vomiting and prostration, coma, a fixed and somewhat contracted pupil, and convulsive movements. (*Ann. Thér.*, 1859, 36.) A fatal case is recorded. (*M. T. G.*, 1867, 26.) The plant was formerly looked upon as a powerful nerve, but it is now out of use. The leaves and wood were given in the *dose* of a drachm (3.9 Gm.) in substance. According to P. Riehl (*D. M. W.*, xxvi, 1900), viscin affords an excellent basis for the making of applications to the skin, a benzene viscin solution mixed with starch affording an excellent plaster mass.

The *American Mistletoe* is the *Phoradendron flavescens*, Nuttall (*Viscum flavescens*, Pursh). It is probably the plant reported as growing upon the elm, by which several children were poisoned. (Henry Dye, *Memphis Med. Recorder*, iv, 344.) The prominent symptoms were vomiting and great thirst followed by frequent discharges of bloody mucus from the bowels, with tenesmus. One of the children was found in a collapsed state, in which death took place. Dye states also that, in other instances, as he had been informed, children had eaten the berries without any ill effect. W. H. Long, confirmed by Lee Payne (*North Carolina Med. Journ.*, vol. vii, 253) asserts (*New Prep.*, ii, 31) that the American mistletoe is a very certain oxytocic, and very efficacious in arresting post-partum and other varieties of *uterine hemorrhage*. He gives a fluidrachm (3.75 Cc.) of the fluidextract every twenty minutes in labor until the effect is produced; every four to six hours in *menorrhagia*.

Vitellus. U. S. 1890. *Yolk of Egg*.—"The yolk of the egg of *Gallus Bankiva*, var. *domestica* Temminck (class *Aves*; order *Galline*)."
U. S. 1890.
The yolk of egg was made official in 1890 because of its use in the glycerite of yolk of egg.

Glyceritum Vitelli. U. S. 1890. *Glycerite of Yolk of Egg*. *Glyconin*.

"Fresh Yolk of Egg, forty-five grammes [or 1 ounce av., 257 grains]; Glycerin, fifty-five grammes [or 1 ounce av., 411 grains], to make one hundred grammes [or 3 ounces av., 231 grains]. Rub the Yolk of Egg, in a mortar, with the Glycerin, gradually added, until they are thoroughly mixed. Then transfer the mixture to a bottle."
U. S. 1890.

Under the name of *Glyconin* there has been employed in France for many years, both for medicinal purposes and for those of the toilet, an emulsion made of glycerin and the yolk of egg. When these two substances are rubbed together, they unite to form a very intimate mixture, which does not separate. It has the consistence of honey, and forms an opaque emulsion with water. It may be preserved almost indefinitely. The usual proportions of the ingredients are four parts of the yolk of egg and five parts of pure glycerin. It has been repeatedly recommended as a basis for cod liver oil and other emulsions. (See also papers by Close in *Proc. A. Ph. A.*, 1884 and 1886.) It is itself not medicinal.

Vulcanite.—For cases of poisoning by *artificial gum* made of vulcanite colored with vermilion, see *Med. Press and Circular*, Dec. 1874.

Warburg's Tincture.—This famous remedy, at first a proprietary medicine, afterwards by the voluntary act of its inventor had its formula revealed. There is so much testimony as to its extraordinary virtues in the severe *remittent* and *pernicious malarial fevers* of India that its powers can scarcely be questioned. After the bowels of the patient in the acutest stage of the disorder have been freely opened, a half ounce of the tincture is given undiluted, all drink being withheld, and at the end of three hours a second half ounce is given in a similar manner. Soon after the second dose a violent, aromatic perspiration comes on, and the fever is usually broken. The remedy is also commended in *collapse* without organic disease. The formula given by Warburg is as follows: Socotrine aloes 1 lb.; rhubarb, angelica fruit, confection of Damocratis, each 4 oz. troy; elecampane, saffron, fennel, prepared chalk, each 2 oz. troy; gentian, zedoary, cubebs, myrrh, camphor, agaric, each, 1 oz. troy. Digest the whole with 500 oz. proof spirit in a water bath for 12 hours, express, add 10 oz. sulphate of quinia, dissolve by the aid of a water bath, cool, and filter.

It is evident that Warburg's Tincture contains various substances which are inert, but the practical difficulty is to determine as to what its extraordinary valuable anti-malarial powers are really due. The formula of Hager—quinine sulphate 1 part, spirit of camphor, 2 parts, elixir proprietatis (P. G.) 22 parts, alcohol 16 parts—does not seem to us to at all represent the tincture. The formula used in the U. S. army, with asserted excellent results in Cuba, has the advantage of yielding a product in tablets, which is as follows: Aqueous extract aloes, 224 grains; rhubarb, 448 grains; angelica seed, 448 grains; elecampane, 224 grains; saffron (Spanish), 224 grains; fennel, 224 grains; gentian, 112 grains; zedoary root, 112 grains; cubeb, 112 grains; myrrh, 112 grains; white agaric, 112 grains; camphor, 112 grains; quinine sulphate, 1280 grains. Exhaust with eight pints of diluted alcohol, or divide into 1024 tablets.

The confection of Damocratis¹ is in the original

¹ *Confectio Damocratis (Mithridatum)* is a combination of thirty aromatic substances mostly obsolete, formerly official in the London Pharmacopœia. We are indebted to Robert Fletcher, of the Surgeon-General's office, for the following formula, taken from the London Pharmacopœia of 1677, p. 100. It is, of course, useless as a pharmaceutical preparation.

MITHRIDATUM.

Myrrhæ Arabicæ,
Croci.
Agarici.
Zingiberis.
Cinnamomi.
Spicæ Nardi (Indian Nard or Spikenard),
Thuris (G. Olibanum).
Sem. Thapsios (water cress seeds), ana drachmas decem.
Seseeleos (*Laserpitium Siler*—heartwort, sermoun-tain).
Opobalsami seu Olei Nucis Moschatæ per expressionem.
Junci odorati (Camel's hay, sweet rush, a dried plant from Turkey).
Stachados Arabicæ (French lavender).
Costi veri (root of *Costus verus* or dulcis),
Galbani.
Terebinthinae Cypricæ (Chian),
Piperis longi.
Castorei.
Succi Hypocistidos (from *Cytinus*, a parasitic plant in France).
Styracis Calamitæ (Gum S.),
Opoponacis.
Fol. Malabathri recentium, seu, ejus defectu, Macis, ana unciam unam.

formula in such small amount that it is hardly possible that it could have any effect. If it be omitted the formula can be very readily followed, and it seems to us that the apothecary should use the original formula with this single alteration when Warburg's Tincture is called for. (See also *Tinctura Antiperiodica*, National Formulary.)
Dose, one to four fluidrachms (3.75–15.0 Cc.).

Whiting.—This is essentially the same as prepared chalk, being made by the pulverization and elutriation of crude chalk. It is used as a coarse paint, and for various purposes in the arts, for which calcium carbonate is requisite. *Paris white* is a variety of the same material.

Winter's Bark. WINTERA. The bark of *Drims Winteri*, Forst. *Cortex Winteranus*. *Ecorce de Winter*, *Cannelle de Magellan*, Fr. *Winter's Zimmt*, G. (Fam. Magnoliacææ).—For description of tree, see *U. S. D.*, 16th edition. The tree is a native of the southern parts of South America, growing along the Strait of Magellan, and extending as far north as Chile. According to Martius, it is found also in Brazil. The bark

Casie lignee veræ,

Pharmacopœia Coll. Reg. Londini. 1677, 125.
The first form of Warburg's Tincture contained a small quantity of *Mithridate*; formula therefore added.

of the tree was brought to England, in the latter part of the sixteenth century, by Captain Winter, who attended Drake on his voyage round the world, and while in the Strait had learned its aromatic and medicinal properties. Since this period, from time to time various barks have appeared in European commerce as Winter's bark, although not any that was the genuine bark. Among those in the London market was at one time the bark of *Cinnamodendron corticosum*, Miers. (Fam. Canelaceæ), of Jamaica, which is pungent like true Winter's bark, but is of a much paler brown color, and resembles canella bark except in the absence of the chalky-white inner surface. Recently this bark has been replaced by the bark of *Croton Malambo*, Karst. (Fam. Euphorbiaceæ), which resembles in color and thickness the bark of the Cinnamodendron, but has a bitter taste and a calamus-like flavor. The following is the description of a specimen which came into the possession of George B. Wood many years since. It corresponds closely with Guibourt's description of commercial Winter's bark. It is in quilled pieces, usually a foot in length and an inch or more in diameter, appearing as if scraped or rubbed on the outside, where the color is pale yellowish or reddish gray, with red elliptical spots. On the inside the color is that of cinnamon, though often blackish. The pieces are sometimes flat and very large. The bark is two or three lines in thickness, hard and compact, and when broken exhibits on the exterior part of the fracture a grayish color, which insensibly passes into reddish or yellowish towards the interior. The powder resembles in color that of Peruvian bark. The odor is aromatic, the taste spicy, pungent, and even burning. P. N. Arata and F. Canzoneri describe a bark which they assert to be genuine Winter's bark from the Strait of Magellan. It was in the form of deeply furrowed, curled-up fragments with an earthy fracture, exhibiting, when in small pieces, an internal reddish-brown coloration. When fresh it had a bitter and pungent taste and an agreeable odor, recalling both turpentine and cloves. The sun-dried bark yielded: water (at 110°), 13.713 per cent.; ash, 3.338 per cent.; soluble in ether, 3.841 per cent.; in alcohol, 6.465 per cent.; in water, 13.981 per cent.; ligneous matter, 49.200 per cent. The ethereal solution contained a peculiar essence, fatty compounds, resins, and waxy matter; the alcoholic extract contained reddish uncrystallizable resins. The *volatile oil* was isolated by distilling the bark with water, exhausting the distillate with petroleum, and distilling off the solvent. The crude oil, amounting to 0.64 per cent. of the weight of the bark employed, was a mixture of several substances. *Winterene*, $C_{15}H_{24}$, is the essential oil separated from this by fractional distillation. It passes over between 260° and 265° C. (500°–509° F.); specific gravity at 13° C. (55.4° F.) = 0.93437. Index of refraction = 1.4931; specific rotatory power at 16° C. (60.8° F.) $[\alpha] = +11.2$. It is readily oxidized on exposure to the air, becoming yellow. The formula $C_{25}H_{40}$ was calculated from the ultimate analysis and vapor density, but the authors consider that the ready oxidizability of winterene and its analogy to similar essences point rather to the formula $C_{15}H_{24}$, which would place it in the group of sesquiterpenes, such as cedrene, cubebene, etc., the boiling points of which are between 250° and 268° C. (482°–514.4° F.). (P. J., June 14, 1890.) The presence of tannic acid and

ferric oxide, according to Henry, serves to distinguish Winter's bark from *Canella alba*, with which it has often been confounded. The bark above described as commercial Winter's bark is destitute of both tannic acid and ferric oxide, and cannot therefore be the bark examined by Henry.¹

The bark of the *Drimys granatensis*, L. f. (now regarded as identical with *D. Winteri*, Forst.), has been imported into London under the name of *Merida coto*, and it has been stated that it contains *cotoin*. It occurs in short pieces of a yellowish-gray color, traversed longitudinally by hard cellular layers, which distinguish it at once from *coto* and *paracoto* bark. Its odor resembles that of true *coto*, but is more feeble. A careful chemical study of it by O. Hesse (P. J., vol. lv.) shows that it contains no *cotoin*, but a crystalline substance, $C_{13}H_{14}O_4$, to which the name of *drimyn* was given. From the leaves Hesse obtained a wax alcohol, *drimol*, $C_{28}H_{58}O_2$. As *Drimys granatensis*, L. f., is recognized as *D. Winteri*, Forst., it is plain that *Merida coto* must be looked upon as a form of Winter's bark coming from Venezuela.

Medicinal Properties and Uses.—Winter's bark is a stimulant aromatic tonic, and was employed by Winter as a remedy for *scurvy*. It may be used in half-drachm (2.0 Gm.) doses for similar purposes with cinnamon or canella alba, but is scarcely known in the medical practice of this country. *Drimys chilensis* of De Candolle, growing in Chile, yields a bark having similar properties (Carson, A. J. P., xix. 81); also *D. aromatica*, F. Muell., of Australia (P. J., xxi.).

Wistaria. *Wistaria chinensis*, DC. (*Kraunhia chinensis*.) (Fam. Leguminosæ.)—Ottow (P. J., Oct. 1886) has obtained from this ornamental leguminous creeper a crystalline poisonous glucoside, *wistarin*.

Withania. *Withania coagulans*, Dun. (*Pu-neria coagulans*, Stock.) *Vegetable Rennet*. (Fam. Solanaceæ.)—This shrub, common in Afghanistan and Northern India, has the property of coagulating milk, and has been used for preparing a vegetable rennet ferment for making cheese. Sheridan Lea found upon examination that the substance which possesses the coagulating power is a ferment closely resembling animal rennet. The active principle is soluble in glycerin, and can be extracted from the seeds by this solvent; the extract possesses strong coagulating powers even in small amounts. Alcohol precipitates the ferment body from its solutions, and the precipitate, after washing with alcohol, may be dissolved again without having lost its coagulating powers. The active principle of the seeds will cause the coagulation of milk when present in very small quantities, the addition of more of the ferment simply increasing the rapidity of the change. The coagulation is not due to the formation of acid by the ferment. If some of the active extract be made neutral or alkaline, and added to neutral milk, a normal clot is formed, and the reaction of the clot remains neutral or faintly alkaline. The clot formed by the action of the ferment is a true clot, resembling in appearance and properties that

¹ For Guibourt's description of true Winter's bark, written in 1850, see 17th edition *J. S. D.* Guibourt also describes the barks of two other species of *Drimys*, those of *D. mestana* and *D. granatensis*, growing respectively in Mexico and Colombia, both of which have considerable resemblance to the preceding. (Tome iii. 681, 682.)

formed by animal rennet, and is not a mere precipitate. Lea prepared an active extract, applicable for cheese making purposes, by grinding the dry seeds very finely in a mill, and extracting them for twenty-four hours with such a volume of 5 per cent. sodium chloride solution that the mass is still fluid after the absorption of water by the fragments of the seeds as they swell up. From this mass the fluid part may be readily separated by using a centrifugal machine (such as is used in sugar refining), and it can then be easily filtered through filter paper; without the centrifugal machine the separation of the fluid from the residue of the seeds is tedious and imperfect; forty grammes of the seeds treated as above, with 150 Cc. of 5 per cent. sodium chloride solution, gave an extract of which 0.25 Cc. clotted 20 Cc. of milk in twenty-five minutes, and 0.1 Cc. clotted a similar portion of milk in one hour. When added in these proportions the curd formed is quite white. The presence of the coloring matter is, however, perhaps on the whole unimportant, since even if a larger quantity of the ferment extract is added in order to obtain a very rapid coagulation, the coloring matter is obtained chiefly in the whey, the curd being white; by adding sufficient common salt to make the percentage up to 15 per cent., and alcohol up to 4 per cent., the preparation would retain its activity very well. (*P. J.*, 1884, 606.)

Woorari. Woorara. Woorali. Urari. Curare. This powerful South American arrow poison was first brought to Europe by the celebrated traveller Waterton; it was in the form of a thick syrup, but as it now occurs in commerce it is a blackish extract, brittle, somewhat resinoid in appearance, encrusting the sides of gourds or little rude earthenware jars, into which it has almost certainly been poured in a liquid state. The drug varies much in strength. It has been variously described. According to the researches of Planchon (*P. J.*, xi. 491), there are really four distinct varieties of curare. 1. That from the Upper Amazon, obtained from the *Strychnos castelneana*, Wedd., and possibly from *S. Yapurensis*, G. Planch. 2. That from the Upper Orinoco, extending towards the Rio Negro, yielded by *S. Gubleri*, G. Planch.; this is the variety spoken of by Humboldt. 3. That of British Guiana, obtained from *S. toxifera*,¹ Schomb., associated with *S. pedunculata*, Benth. (*S. schomburgkiana*, Klotzsch), and *S. cogens*, Benth. 4. That of French Guiana, made out of *S. crevauxiana*, Baill. (*S. Crevauxii*, G. Planch.). If this classification be correct, it is very important to distinguish the varieties of the woorari; this at present cannot be done. H. C. Wood has received, however, two distinct wooraris, one said to come from the Upper Amazon, therefore No. 1 of Planchon, and the other believed to come from the Orinoco. They are distinguished by the former being free from and the latter full of ants, evidently put in while the poison was liquid. The preparation of woorari has been witnessed by various travellers and variously described. (See *P. J.*, xvi. 502; *B. F. M. R.*, Oct. 1865; *P. J.*, x. 1881.) It usually consists in making a decoction and finally extract of various plants, including

the active *Strychnos*. Jobert asserts that the Tecuma Indians use, besides *S. castelneana*, Weddell, *Cocculus toxiferus* and an arum (*Taya*), which he found to be very poisonous. According to Kobert (*Ph. Ztg.*, June, 1885), *Malouetia nitida*, Spruce (Fam. Apocynaceae), or *Guachamacaca*, a plant which is abundant in the Orinoco and Rio Negro districts, enters largely into the composition of curare. The alkaloid, *guachamacine*, isolated by T. Schiffer in 1883, is very closely allied to, if it be not identical with, curarine, in both its chemical and its physiological activity. It is entirely possible that the varieties of woorari vary in their alkaloid and their physiological properties. Allied, it may be, to the third variety of woorari are the arrow poisons brought by W. S. W. Ruschenberger from Colombia, and studied by W. A. Hammond and S. Weir Mitchell. (*Am. J. M. S.*, July, 1859.) *Corroval* was in dark brown lumps, having the appearance of a vegetable extract, and of an intensely bitter and persistent taste. Under the microscope it presented the appearance of vegetable remains, but nothing animal. It yielded its active properties to water and alcohol, and was found to depend for its activity upon a peculiar alkaloid, *corrovaline*. In a few minutes after the introduction of the poison through a wound, paralytic phenomena became obvious, and the animal soon died, without preliminary spasm or convulsions. But the heart, instead of continuing to act after apparent death, had entirely ceased to beat, and had quite lost its irritability, so that it could not be excited by galvanism. They inferred that the action of the poison is directly and primarily on the heart, possibly through the ganglia contained in its tissue. There was no evidence whatever, either chemical or physiological, of the presence of strychnine in the poison. *Vao* or *bao* was a vegetable extract containing corrovaline, and apparently only a diluted or adulterated corroval. In 1893 Joseph Tillie obtained arrows from New Granada the poison on which affected chiefly the muscles, and it would seem, therefore, that under the name of woorari are used in South America arrow poisons much more allied to *strophanthus* in their physiological activity than to the true wooraris, which do not attack the voluntary or involuntary muscles. To such poisons the name of *corroval* should at present be applied. The term curare has in itself no specific meaning, since, according to Whiteford, it is simply the Indian word for poison. It is plain that the poisons coming from South America under the name of woorari are various, although in appearance the same, and that at present, therefore, woorari can hardly be used in practical medicine.

In 1898 Boehm classified the curares of the markets as *Tubocurare*, originating from the Amazon, preserved in hollow bamboo canes, and said to contain about 9 to 11 per cent. of *tubocourarine* as its poisonous constituent; *Gourd curare*, derived from *Strychnos toxifera*, very rarely met with, and having curarine and a second alkaloid soluble in ether for its active principle; *Jor curare*, obtained from *Strychnos castelneana*, also exceedingly rare in the European markets, containing three alkaloids,—*proto-curine*, having a feeble curare action; the non-poisonous *proto-curidine*; and *protocourarine*, which is more actively poisonous than is curarine (*Ph. Ztg.*, xlii. 41).

The attempts first made to isolate the poisonous principle of woorari were without satisfactory re-

¹ The bark of the *Strychnos toxifera* has been chemically examined by Villiers, who finds that its purified extract resembles in its chemical and physiological relations ordinary curarine. He was not able, however, to obtain the pure alkaloid. (*J. P. C.*, fifth series, vol. xi.)

sults. Heintz succeeded in obtaining the poison in an exceedingly concentrated form, but not entirely separated from other principles. (*Am. Med. Gaz.*, vii. 6.) In 1828 Boussingault and Roulin separated a substance which they regarded as an alkaloid, but which neither they nor other chemists obtained in a crystalline state. Pure concentrated sulphuric acid gives with the curare alkaloids a very durable, magnificent blue color, which is not the case with strychnine. With potassium dichromate the same acid develops the same violet color as with strychnine, but much more persistent. Concentrated nitric acid renders it purple. By these tests curare may be readily detected in the fluids of animals poisoned with it. (*J. P. C.*, 4e sér., ii. 296.) Within the last few years R. Boehm has finally isolated the two bases, *curarine* (also called *tubo-curarine* from its source in the curare packed in bamboo tubes), $C_{19}H_{21}NO_4$, and *curine*, $C_{18}H_{19}NO_4$. The free tubo-curarine forms an amorphous brown-red mass. Boehm (*Ber. d. Chem. Ges.*, xx. 143) states that curine exists in many specimens of curare; it may also be obtained from the aqueous extract of curare. It is much less poisonous than the accompanying curarine. Curine is a crystalline powder fusing at 161°C . (321.8°F .), slightly soluble in cold water, freely soluble in alcohol, chloroform, and dilute acids. It forms a voluminous white precipitate with metaphosphoric acid.

Woorari is one of those poisons whose active principle passes through animal membranes with difficulty, and hence when given by the stomach or rectum it acts very slowly, and in some cases elimination may proceed so rapidly that no marked influence is exerted, because not enough of the alkaloid is in the blood at any one time. There is also some reason for believing that the alkaloid is destroyed in the liver. When injected into a vein, or introduced by the hypodermic needle or the poisoned arrow into the cellular tissue, it acts with great promptness. The symptoms caused are progressive loss of muscular power, the animal growing weaker and weaker, the respirations becoming more and more feeble, until death by asphyxia results. Not rarely there are marked muscular twitchings, or even convulsive movements, which Vulpian asserts (*Leçons Subs. Toxic.*, 1881, 202) are not due to the asphyxia, because they are not prevented by artificial respiration. They are probably of centric origin, since Tillie (*A. E. P. P.*, xxvii.) has shown that the drug first excites the spinal cord, although such action is masked by the paralysis of the motor nerves. The heart usually continues beating after cessation of breathing, and only very large doses of the poison affect early the arterial pressure. It has indeed very little action upon the cardiac or vasomotor apparatus unless the dose be very large, when the blood pressure sinks from depression of the peripheral vasomotor nerves (Tillie), the cardiac fibres of the vagi also suffer (Dogiel and Nikolski). The failure of muscular power and loss of reflex activity are not due to any influence upon the nerve centres or the muscles, but to paralysis of the motor nerves; it is probable, as Vulpian believes, that it is the extreme peripheral endings of these which first suffer. At a certain stage of the poisoning, response occurs in the tributary muscle when a nerve is galvanized, although reflex and voluntary impulses are unable to force a passage to the muscles. The sensory, vasomotor, and inhibitory nerves are not affected unless by enormous doses. Couty and De

Lacuda have brought forward some evidence to show that the muscles do not escape as absolutely as has been believed. (*Schwalbe's Jahresb.*, 1881, 203.) Death has generally been attributed to paralysis of the respiratory nerves, but Dogiel and Nikolski are of the opinion that death is due to the respiratory centres being paralyzed.

Glycosuria has been frequently noticed as the result of woorari poisoning in animals. According to the experiments of K. Morishima, in frogs poisoned either with curarine or protocurarine it is only an occasional phenomenon. It is apparently not connected with the amount of glycogen in the liver or in the muscles (*A. E. P. P.*, xlii. 1899). In regard to action upon the bodily temperature the evidence is somewhat contradictory. Bernard noticed an extraordinary rise, but, according to more recent observations, the temperature of the central portions of the body falls, while that of the extremities, and sometimes even of the lower rectum, rises. Voisin and Liouville divide the effects on the human subject into two classes, according to their severity. The milder symptoms are chiefly exhibited in the circulatory system. The pulse is increased in force and frequency, the respiration is rendered somewhat more frequent, the temperature is slightly elevated, perspirations sometimes occur, and the urine is augmented in quantity, is remarkably light-colored, and contains glucose. From larger quantities of the poison violent febrile phenomena occur, commencing with the characteristic symptoms of a severe chill. There are shivering, chattering of the teeth, sensations of severe cold, cutis anserina, startings, and general trembling, with small and rapid pulse, anxiety, sighing, etc. The power of the lower extremities rapidly diminishes or quite ceases, coordination of motion is disturbed, and sometimes the patient is unable to move the legs. Thirst, headache, insomnia, and sometimes diuresis, are added to the other symptoms. The first coldness is followed by a hot skin, frequent and full pulse, redness of the surface, injected conjunctiva, and a profuse sweat. The paralysis of the lower extremities continues generally for a few minutes, at most for an hour; but care was taken to arrest the action of the poison by compressing the vessels above the point of insertion. The fever continues longer; sometimes, when the dose is large, for five or six days, gradually diminishing. The elimination of the poison by the kidneys appears to cease in about twenty-four hours. In cases of poisoning from the injection of woorari, a ligature around the limb between the place of injection and the heart, the free exhibition of diluents and evacuants, and artificial respiration when required, are the measures recommended. (*Ed. M. J.*, 1867, 667.)

As a remedy curare has very little value, even in *tetanus*, *hydrophobia*, and other severe *convulsive affections*; it will undoubtedly quiet the spasm, but does not have any direct curative influence upon the disease, which is due to an irritation of the centres and not of the nerve trunks. According to the elaborate experiments of Du Cazal (*A. G. M.*, Sept. 1869), from one-fourteenth to one-seventh of a grain (0.005–0.01 Gm.) daily were borne by a dog without inconvenience; at the dose of ten milligrammes the characteristic phenomena began to show themselves, but disappeared in a few hours; with fourteen milligrammes the animal perished. For man the doses administered by subcutaneous injection were from one-sixth to

three-fourths of a grain (0.01–0.05 Gm.). From these quantities, the appearance of glucose in the urine proved the presence of the poison in the system, and some slight characteristic symptoms, as dizziness, headache, vertigo, general lassitude, have appeared, but without any serious disturbance of the locomotor apparatus. Jousset and Bellesme prepare an infusion in the proportion of one part of the medicine to ten parts of boiling water, and after filtration, inject subcutaneously, at short intervals, a quantity of the infusion equivalent to half a centigramme (about one-thirtieth of a grain), to be increased or diminished according to its effects. (*Ann. Thé.*, 1866, 37.)

According to Bernard, *curarine* is at least twenty times as strong as curare, and should be given in proportionate dose. According to the experiments of Joseph Tillie, *curine* has no influence upon the motor nerves, but acts both in the frog and in the mammal upon the heart, belonging physiologically to the digitalis group. Boehm states that the presence of curine in curare can be recognized by the white precipitate made by metaphosphoric acid.

Wrightia. *Wrightia zeylanica*, R. Br. *Wrightia antidysenterica*, R. Br. *Nerium antidysentericum*, L. (Fam. Apocynaceæ.)—Under the names of *Conessi bark*, *Tellicherry bark*, and *Codaga pala*, a spongy, rusty-colored, bitter bark of this apocynaceous tree was formerly used in Europe as a remedy in *dysentery* and *diarrhoea*, and is said still to be largely employed by the native practitioners of India. Stenhouse obtained from the seeds, besides a fixed oil which they contain in large quantity, a peculiar bitter principle, called by him *wrightine*, which, though uncrystallizable and forming uncrystallizable compounds with the acids, has claims to be ranked with the alkaloids. (See *P. J.*, 1864, 493.) Hains had previously obtained the same alkaloid, and described it under the name of *conessine*. (*P. J.* (2), vi. 432.) The alkaloid conessine is now a commercial product prepared by Merck, and the formula $C_{12}H_{20}N$ is given it. It occurs in delicate white interlaced masses of crystals, melting at $121^{\circ} C.$ ($249.8^{\circ} F.$), sparingly soluble in water, readily so in alcohol. A small quantity rubbed with a few drops of concentrated sulphuric acid affords on the addition of nitric acid a golden and finally orange-yellow color. We are not aware that the medicinal properties of this have been investigated.

A species of the allied genus *Holarrhena* (*H. africana*, DC.), is stated by German missionaries to be used in parts of tropical Africa in *dysentery*. Polstorff and Schirmer (*Ber. d. Chem. Ges.*, 1886, 78) prepared the alkaloid both from *Holarrhena africana* and from *Wrightia zeylanica*, finding it to be identical in the two cases. They gave it the formula $C_{12}H_{20}N$, and state that it is a light white powder, melting at $121.5^{\circ} C.$ ($251^{\circ} F.$), sparingly soluble in water, freely soluble in alcohol, ether, chloroform, and benzene. When oxidized by iodic acid in sulphuric acid solution, conessine is changed to *oxyconessine*, $C_{12}H_{20}NO$.

Wurru.—Under the name of *Vars*, *Wars*, or *Wurru*, a powder somewhat similar to kamala has been used as an anthelmintic in Southern Arabia, and exported into commerce from Aden. It is believed to be the product of *Hemigia grahamiana* (*P. J.*, Sept. 1887). It is composed of cylindrical or subconical grains, 170 to 200 Mm. long by 70 to 100 broad, in three or four tiers.

Xanthin Compounds.—The organic radical xanthin, or *diawypurin*, yields the following compounds which are interesting therapeutically:

(1) Trimethylxanthin (caffeine), $C_8O_2N_4H$ (CH_3)₃.

(2) Three isomeric dimethylxanthins: $C_8O_2N_4H_2(CH_3)_2$.

1: 7 Dimethylxanthin, paraxanthin.

1: 3 Dimethylxanthin, theophylline (theocine).

3: 7 Dimethylxanthin, theobromine.

All three of the dimethylxanthins are said to surpass the trimethyl compound as diuretics. Of the xanthin compounds caffeine and theobromine have elsewhere been considered. *Paraxanthin* is not a commercial drug, but according to Dreser-Elberfeld it is an active diuretic.

Theophylline. *Theocine*.—Theophylline was first isolated from tea leaves by Kossel, but in such minute quantities that it was not a commercial product until the discovery by Traube that it could be produced by synthesis, resulting in its being put upon the market under the name of *theocine*. It is a crystalline substance soluble in 179 parts of water at $18^{\circ} C.$ ($64.4^{\circ} F.$), in 85 parts at $37^{\circ} C.$ ($98.6^{\circ} F.$).

Theocine was first brought forward by Minkowski as a very active diuretic, and has been reported upon by a number of German clinicians. It is said to be about as poisonous as caffeine, but distinctly more active than is either caffeine or theobromine as a diuretic. It has been used in both *cardiac* and *renal diseases* with success. It sometimes causes gastric irritation and in some cases severe vomiting, also headache and general malaise have been reported. The system usually, in a short time, becomes accustomed to its use, so that it fails after a time to produce any therapeutic effect. Its maximum action is commonly apparent the second or third day of its ingestion. *Dose*, 7.5 to 18 grains (0.5–1.2 Gm.) may be given in divided doses every twenty-four hours.

Xanthium.—Guichard believes that he has found an alkaloid in the *X. speciosum*. (*P. J.*, vii. 249.) In the *Xanthium Strumarium*, L., *Cocklebur* or *Clotbur*, which is common both in Europe and in America, A. Zander believes that he has found a glucoside, *xanthostrumarin*. M. V. Cheatham thinks that there is a second active principle. (See *A. J. P.*, vol. xi. 271, vol. xiv. 134.) Clotbur is stated to be an active styptic, both local and general. *Dose*, of the fluidextract, from one to two fluidrachms (3.75–7.5 Cc.).

Xanthorrhiza. *Yellow-root*. *Shrub Yellow-root*. *Xanthorrhiza apifolia*, L'Herit. (*X. tinctoria*, Woodhouse).—This is a ranunculaceous shrub, two or three feet in height, with a horizontal root, which sends off numerous suckers. The stem is simple, rather thicker than a goose quill, with a smooth bark and bright yellow wood. The leaves, which stand thickly at the upper part of the stem, are compound, consisting of several ovate-lanceolate, acute, doubly serrate leaflets, sessile upon a long petiole, which embraces the stem at its base. The flowers are small, purple, and disposed in long, drooping, divided racemes, placed immediately below the first leaves. The yellow-root grows in the interior of the Southern and in the Western States. Nuttall found it abundant on the banks of the Ohio. It flowers in April. The root was formerly in the Secondary List of the U. S. Pharmacopœia, but the bark of the stem possesses the same virtues. The root is from three inches to a foot or more in length, and about half an inch in thickness near the stem. It shrinks somewhat in

drying, and, as found in commerce, is in slender pieces of various lengths, diminishing from three or four lines in thickness to the dimensions of a knitting needle, wrinkled longitudinally, with a light yellowish-brown, easily separable epidermis, a thick, hard, bright yellow woody portion, and a very slender central pith. It is inodorous, and of a simple but extremely bitter taste. It imparts its color and taste to water. The infusion is not affected by ferric salts. J. Dyson Perrins found *berberine* in it. (*P. J.*, May, 1862.) Samuel S. Jones believed that he had proved the existence in the drug of a second alkaloid. (*A. J. P.*, vol. xvi. 1861.) *Xanthorrhiza* possesses properties closely analogous to those of *calumba*, *quassia*, and other simple tonic bitters, and may be used for the same purposes and in the same manner. Woodhouse employed it in the dose of forty grains (2.6 Gm.).

Xanthorrhæa Resins. *Gum Acaroides.* *Gum Acroides.*—Yellow and reddish resinous substances, the products of different species of *Xanthorrhæa* (Fam. Liliaceæ), have been introduced into England from Australia. They are obtained by spontaneous exudation from the stems of the plants, which are usually shrubs. The *yellow variety* (from *X. media*, R. Br., syn. *X. hastilis*, *X. resinosa*, Sm.) is in tears, in flattish pieces having on one side the mark of the stem, or in masses of various size and irregular shape. It has a reddish-yellow color, resembling gamboge when broken, and when heated emits a fragrant odor like that of Tolu balsam. It contains resin, cinnamic and benzoic acids, and a trace of volatile oil, and may therefore be ranked among the balsams. When heated with nitric acid, it yields a large product of picric acid. In medicinal properties it is said to bear a close resemblance to storax and the balsam of Tolu. A tincture, made in the proportion of two ounces to a pint of alcohol, may be given in the dose of one or two fluidrachms. The *red variety* (from *X. australis*, R. Br.) resembles dragon's blood in color, and appears to be analogous to the other variety in properties. (See *A. J. P.*, 1881; also *A. J. P.*, vol. xv., and *D. C.*, 1895, 83.) These resins have been introduced as a shellac substitute in varnish making.

Xylene. *Xylol.* *Xylène*, Fr. *Xylol*, G. $C_6H_4(CH_3)_2$.—There are three isomeric hydrocarbons of this name, the ortho-, meta-, and para-xylene respectively, all contained in coal tar. A mixture of them was first extracted from naphtha by Hugo Müller, and was brought forward by Zuelzer as a specific in *small pox*, but is useless. (*P. J.*, 1872, 623.) It is largely used as a solvent by microscopists.

Yeast. *Cerevisiæ Fermentum.* *Beer Yeast.*—The ferment obtained in brewing beer, and produced by *Saccharomyces* (*Torula*, Turpin) *cerevisiæ*, Meyen, was dismissed from the U. S. Pharmacopœia in 1880, from the British in 1898. Two well-marked varieties of the *Saccharomyces cerevisiæ* have been recognized. The one is the most active at the ordinary temperature (16° – 20° C., 60.8° – 68° F.), and carries through its fermentative work in from three to four days; the other works at a lower temperature (6° – 8° C., 42.8° – 46.4° F.), and the fermentation is much slower. The first placed in a saccharine liquid is carried by the carbon dioxide which it liberates to the surface of the liquid, where it continues its activity; it is, therefore, known as a *surface* or *top yeast*. The second, on the contrary, is not car-

ried up, and rests during its entire activity on the bottom of the fermenting vessel, and is hence called a *bottom yeast*. Two quite distinct methods of beer brewing are practised, depending upon the use of the one or the other of these varieties of yeast. (For fuller information as to the nature of yeast and its conditions of culture and activity, see Sadtler's *Industrial Organic Chemistry*, Philadelphia, 3d ed., 1900, 185 et seq.)

Yeast is a flocculent, frothy, somewhat viscid semi-fluid, of a dirty yellowish color, a sour vinous odor, and a bitter taste. Exposed to a moderate heat it loses its liquid portion, becomes dry, hard, and brittle, and may in this state be preserved for a long time, though with the loss of much of its peculiar power. *Yeast cakes* are made by putting yeast into sacks, washing it with water, then submitting it to pressure, and ultimately drying it (*Ibid.*, 225); *compressed yeast*, the undried product, is now largely used.

Yeast is insoluble in alcohol or water. Its ultimate composition, according to Schlossberger (*Ann. Ch. Ph.*, 51, 199), is carbon 49.9 per cent., hydrogen 6.6 per cent., nitrogen 12.1 per cent., and oxygen 31.4 per cent. Its proximate constituents are albuminoids, cellulose, fats, and resinous substances.

The chief function of yeast is the inducing of the vinous fermentation, in which are produced alcohol and carbon dioxide, and various other substances in smaller or larger proportions. Pasteur has shown that while from 94 to 95 per cent. of the sugar decomposes into ethyl alcohol and carbon dioxide, the other 5 or 6 per cent. decomposes by secondary reactions, yielding glycerin from 2.5 to 3.6 per cent. and succinic acid from 0.4 to 0.7 per cent. The higher homologues of ethyl alcohol are also produced in small amount, forming fusel oil or raw spirit.

The activity of yeast is due to the presence of a microscopic fungus, first discovered in it by Leuwenhoek in 1680. As originally announced by Thénard in 1803, this yeast plant is ordinarily the cause of the alcoholic fermentation. It consists of numerous cells, irregular, roundish, or cylindrical in shape, separate, jointed into rows, or budding one from the other. It is most probable that the yeast plant is the mycelium, or early vegetative stage, of more than one species of mucor or mould; and some authorities recognize various species of the yeast fungus. The name *Torula cerevisiæ* was first given to the yeast plant, which was subsequently called *Mycoderma vini*; Reess, in his elaborate work (*Alkoholgährungsphilze*, Leipsic, 1870), made a distinct genus of it, *Saccharomyces*, including many species.

According to Albert Buchner and Rapp, a dried yeast which retains its activity on keeping is obtained as follows: The yeast is freed from water as much as possible by expression, immersed in acetone and rubbed through a sieve. The acetone is decanted, renewed, again decanted, and the residue collected by the aid of a suction filter, then treated with ether for three minutes, and this removed in the same way, after which the yeast is spread out to dry, the drying being completed at a temperature of 45° C. (113° F.). Dried yeast, so obtained, is an almost white powder. (*Ph. Centrall.*, 1903, 36.)

According to Casagrandi, *Saccharomyces ruber*, previously discovered by Demme, produces a *red yeast* which ferments glucose very readily, developing a red pigment. This *saccharomyces* was found pathogenic to various animals, and when

put into milk so modified that liquid as to convert it into a pronounced intestinal irritant. (P. J., Jan. 1898.) A number of yeasts are used in China and Java whose fundamental plants are different from those of the European yeast. See P. J., vol. xlvii.

As a stimulant in *typhoid*, *hectic*, and other low fevers, yeast was formerly employed to a considerable extent, as much as a pint of it being taken within the twenty-four hours. This use of it did not rest upon any scientific basis and has altogether ceased. On the other hand, the employment of yeast in the treatment of various infections has recently received great support from the experiments of Landau (D. M. W., 1899, 11), of Gelli (Corriere Sanitario, 1899, 46) of Hallion and Carrion, of Nobécourt (S. M., 1901), of Durand (Lyons Méd., 1902), and of others, which experiments demonstrate that yeast has active germicidal properties. It is now employed as a local remedy in various infectious inflammations, and has been especially commended in the treatment of gonorrhœa of the female, the yeast being injected so as to fill the vagina and retained in place for some hours by means of a plug. The application should at first be made every other day; subsequently at longer intervals. There is further much testimony to show that yeast exerts, even when given internally, a germicidal action; it has long been used in *furunculosis*, and recently has been highly commended in *purpura*, *cholera*, *dysentery*, and other conditions of the alimentary canal dependent upon the presence of organisms. From two to four ounces of it may be taken three or four times a day. Locally it may be applied *ad libitum*. Dried yeast has been much used in France internally under the name of *levurine*, and it is probable that the ordinary yeast cake of American bakers may well be substituted for yeast.

Yohimbine.—This is an alkaloid which is obtained from the bark of *Corynanthe Yohimbi* (Schumann, Notizblatt der Bot. Gart. in Museum zu Berlin, No. 25, Bd. 3), a rubiaceous tree growing in the Southern Cameroons district in Africa. The bark is stated to be 8 to 10 Mm. thick, with an external corky layer of a gray-brown color covered with isolated lichens. It shows numerous longitudinal and transverse fissures like some old specimens of cinchona bark. The transverse fracture is of a uniform yellowish-brown color, and presents short, soft fibres like rough velvet.

The alkaloid has been obtained in white needles melting at 234° C. (453.2° F.), and having the composition $C_{22}H_{30}N_2O_4$.

It was originally investigated by Oberwarth and Lowry (V. A. P. A., vol. 153, and B. K. W., No. 42, 1900), who found it to be in animals and also in man a very active excitant to the sexual organs and functions. On the other hand, Kravkoff, as the result of experiments upon the lower animals and upon man, concluded that it has no aphrodisiac effects and frequently produces nausea, salivation, irritability, and other disagreeable results. It has been used, however, by numerous clinicians in *neurasthenic impotence*, with reports which are generally favorable to its influence. (For literature, see M. R., 1901, 1902.) It is said to be of no value when the impotence depends upon organic nerve trouble, and to be harmful when it is caused by chronic inflammatory disease of the sexual organs or of the prostate gland. Dose, of the hydrochloride, 0.005 Gm. (1-12th grain),

either in tablet or solution, three or four times a day. Yohimbine has also been employed in a 1 per cent. solution hypodermically.

Zedoary. *Radix Zedoarix.* *Rhizoma Zedoariae*, P. G. Zedoaire, Fr. *Zitterwurz*, G.—There are two kinds of zedoary, the long and the round, distinguished by the old official titles of *radix zedoariae longæ* and *radix zedoariae rotundæ*; the former produced by *Curcuma aromatica*, Salisb. (*O. Zedoaria*, Roxb.), the latter, as some suppose, by *Kæmpferia rotunda*, L., but, according to others, by the *Curcuma Zedoaria*, Rosc. (*O. Zerumbet*, Roxb.), all of the fam. Scitamineaceæ. Both kinds come from the East Indies. The long zedoary is in slices, from a. inch and a half to three inches in length, and from half an inch to an inch thick, obtuse at the extremities and exhibiting the remains of the radical fibres. The round is also usually in slices, which are the sections of a roundish root, ending in a point beneath, and divided longitudinally into two parts, each of which is flat on one side, convex on the other, and heart-shaped in its outline. Sometimes the root of the latter variety is entire, and sometimes in quarters instead of halves. It is marked with circular rings on the convex surface, and, like the former, with small projecting points which are the remains of radical fibres. Both are grayish white on the outside, yellowish brown within, hard, compact, of an agreeable aromatic odor, and a bitterish, pungent, camphorous taste. The round, however, is less spicy than the long. They yield a volatile oil, when distilled with water, and contain a pungent soft resin and bitter extractive. Zedoary is a warm, stimulating aromatic, useful in flatulent colic and debility of the digestive organs. It is not now employed, as it produces no effects which cannot be as well or better obtained from ginger. The dose is from ten grains to half a drachm (0.65–2.0 Gm.).

Zerechit. *Tschuking.* *Landtia Schimper*, Benth. and Hook. (*Ubica Schimper*, J. Gay, *Arctotis Schimper*, O. Kze.)—The leaves, flowers and fruit of an Abyssinian composite. (See Proc. A. Ph. A., xxvi. 228.)

Zerumbet. *Cassumuniar.*—Under these names an East India root was formerly used, having some analogy in sensible and medicinal properties to ginger, and ascribed to the *Zingiber Zerumbet* of Roscoe. Some consider the *cassumuniar* as a distinct root, and refer it to the *Zingiber Cassumuniar* of Roxburgh. The difference of opinion is of little importance, as neither of the roots is to be found in the markets. By some authors the zerumbet has been erroneously confounded with the round zedoary. Geiger describes it as in pieces of the size of a fig or larger, externally grayish brown and wrinkled, internally yellowish, hard and tough, of a biting, aromatic taste, and a spicy odor.

Zinc and Potassium Cyanide. *Zinci et Potassii Cyanidum.* $K_2Zn(CN)_4$.—Made by adding zinc cyanide to solution of potassium cyanide, evaporating and crystallizing. The salt possesses a sweet and metallic taste and is used for the same purposes as zinc cyanide in from $\frac{1}{8}$ to $\frac{1}{2}$ grain (0.008–0.032 Gm.) doses.

Zinc Borate. *Zinci Boras.* $ZnB_4O_7 + 7H_2O$. Prepared by mixing an aqueous solution of zinc sulphate (1 in 10) with one of borax (1 in 25), and collecting the precipitate. Used as an antiseptic dusting powder.

Zinc Cyanide. *Zinci Cyanidum.* $ZnCy_2$.—This cyanide is precipitated as a white insoluble

powder, by adding cautiously, until it ceases to produce a precipitate, a recently filtered solution of potassium cyanide to a solution of zinc sulphate. It is used in Germany as a substitute for hydrocyanic acid, and is said to be anthelmintic. It has been recommended by Lashkevich in cardiac neuroses in doses of from one-tenth to one-eighth grain (0.006–0.008 Gm.) three times a day. It has been employed in *epilepsy*, *chorea*, and *neuralgia*, in several *painful affections of the stomach*, and in the *colics attendant on difficult menstruation*. The dose is a quarter of a grain (0.016 Gm.), gradually increased to a grain and a half (0.096 Gm.), given in mixture. It is official in the French Codex.

Zinc Ferrocyanide. *Zinci Ferrocyanidum.* $\text{Zn}_2\text{FeCy}_6 + 3\text{H}_2\text{O}$.—Formed by double decomposition between hot solutions of potassium ferrocyanide and zinc sulphate. It is precipitated as a white powder. It has similar medicinal properties to those of the cyanide, and is used in the same diseases. The dose is from one to four grains (0.065–0.26 Gm.), given in pill. (See *Zinc Cyanide*, p. 1701.)

Zinc Lactate. *Zinci Lactas.* $\text{Zn}(\text{C}_3\text{H}_5\text{O}_2)_2 + 3\text{H}_2\text{O}$.—This salt is used by Herpin in doses of two grains (0.13 Gm.), three times a day, gradually increased to ten grains (0.65 Gm.) a day, as a substitute for zinc oxide in *epilepsy*. For its physical properties and methods of preparation see 16th edition *U. S. D.*

Zinc Permanganate. *Zinci Permanganas.* *Zinkpermanganat, Uebermangansures Zink.* $\text{G. Zn}(\text{MnO}_4)_2 + 6\text{H}_2\text{O}$.—Made by precipitating barium permanganate with zinc sulphate, using exact molecular proportions. It forms almost black deliquescent crystals, giving off oxygen even more readily than potassium permanganate. It is used as an astringent and antiseptic application.

Zinc Phosphate. *Zinci Phosphas.* *Trizincic Orthophosphate.* $\text{Zn}_3\text{P}_2\text{O}_8 + 2\text{H}_2\text{O}$.—Barnes of London, has brought forward this salt of zinc as having special advantages over other salts of the same metal in the treatment of *nervous diseases*, peculiarly useful in the *insanity* occurring in the convalescence from fevers, in which he associates it with quinine, and in *epilepsy* attended by *disorder of the uterine functions*. Zinc phosphate may be prepared by the mutual reaction of zinc sulphate and an alkaline phosphate. Zinc phosphate is a white powder, insoluble in water but soluble in acids.

Zinc Phosphide. *Zinci Phosphidum.* *U. S.* 1890. $\text{Zn}_3\text{P}_2 = 256.24$.

According to Hager, zinc phosphide was first prepared by Marggraf in 1740. It was formerly made by fusing, in a bath of iron filings, 74 parts of pure zinc, and adding gradually, in small pieces, 26 parts of dry phosphorus. This process gives good results only in small quantities (10 to 20 Gm.). A more recent process is to pass vapors of phosphorus in a current of dry hydrogen over fused zinc. The product is a spongy, gray mass, of metallic appearance, containing rhomboidal crystals, and when powdered resembling somewhat reduced iron. The particles of metallic zinc should be separated. Its sp. gr. is 4.72. "Zinc phosphide should be kept in small, glass-stoppered vials." *U. S.* 1890.

It is thus described in the *U. S. Pharmacopœia* of 1890: "A gritty powder of a dark gray color, or crystalline fragments of a dark, metallic lustre, and having a faint odor and taste of phosphorus. In contact with the air it slowly emits phospho-

rous vapor. Insoluble in water or alcohol. Soluble in diluted hydrochloric or sulphuric acid with evolution of hydrogen phosphide. When strongly heated, with exclusion of air, it melts and finally sublimates. When heated in air, it becomes oxidized to zinc phosphate. If 0.5 Gm. of Zinc Phosphide be dissolved in 15 Cc. of diluted hydrochloric acid, heat being applied to expel all of the hydrogen phosphide gas, a clear solution should result, leaving no residue (absence of *insoluble impurities*). A portion of this solution should yield a pure white precipitate with potassium ferrocyanide test-solution (absence of *iron* or *copper*); or with ammonium sulphide test-solution (absence of *lead* or *copper*). If another portion of this solution be mixed with an equal volume of hydrogen sulphide test-solution, no color or turbidity should appear (absence of *arsenic*, *cadmium*, *lead*, *copper*, etc.)." For a method of assay of zinc phosphide, see *N. R.*, June, 1879.

It has been proved by direct experiment upon animals, as well as by clinical experience, that zinc phosphide affects the system physiologically and therapeutically in exactly the same manner as does phosphorus, and it is employed in medicine as a substitute for that element. Theoretically, each grain of the phosphide contains nearly a quarter of a grain of phosphorus. It is asserted in the journals to have been administered in doses of one or even two grains; but of the pure salt such amounts would be extremely dangerous; the commencing dose is one-twentieth of a grain (0.003 Gm.).

Zinc Salicylate. *Zinci Salicylas.* *Zinksalicylat.* $\text{G. Zn}(\text{C}_6\text{H}_4\text{OH.CO}_2)_2 + \text{H}_2\text{O}$.—Made by boiling together molecular proportions of sodium salicylate and zinc sulphate, cooling, washing the crystals and recrystallizing from hot water. In the form of long satiny needle-like crystals, having a sweet but astringent and bitter taste. It is soluble in about 20 parts of cold water. Zinc salicylate is an astringent and antiseptic, a solution (1 to 5 grains in one fluidounce) is used in *ophthalmia* and *gonorrhœa*.

Zinc Subgallate. *Zinci Subgallas.*—An odorless powder containing 44 per cent. of zinc oxide and 56 per cent. of gallic acid. Internally it is used in intestinal disorders as an antiferment in doses of from one-half to four grains (0.032–0.26 Gm.). Externally it has been used in skin diseases.

Zinc Sulphite. *Zinci Sulphis.* $\text{ZnSO}_3 + 2\text{H}_2\text{O}$. Made by precipitating a solution of zinc sulphate with sodium sulphite, collecting, washing and drying the precipitate. A white crystalline powder, soluble in about 600 parts of water.

Zizyphus. *Zizyphus sativa*, Gaertn. (*Z. vulgaris*, Lamarek.) *Jujube*, Fr. *Brustbeeren*, *Juden-dornbeeren*, G.—A shrub, or small tree, of the fam. Rhamnaceæ, growing on the shores of the Mediterranean, and cultivated in Italy, Spain, and the south of France. The fruit is the part used. This consists of oval drupes, of the size of a large olive, with a thin, coriaceous, red or reddish-brown skin, a yellowish, sweet, acidulous pulp, and an oblong, pointed stone in the centre. These have the name of *jujubæ*. By drying, their pulp becomes softer and sweeter, and acquires a vinous taste, evincing the commencement of fermentation. They are nutritive and demulcent, and are used in the form of decoction in *pectorals complaints*. *Jujube paste* consists properly of gum arabic and sugar, dissolved in a decoction of this fruit, and evaporated to the proper consistence. As a de-

mulcent it is in no respect superior to a paste made with gum arabic and sugar alone, and the preparation formerly sold in this country under the name contains in fact none of the fruit. The fruits of two other species, *Z. Lotus*, Lam., growing in the north of Africa, and *Z. Jujuba*, Lam., a native of the East Indies, possess properties similar to those of the *Z. sativa*, and are used as food by the inhabitants of the countries where they grow. The *Zizyphus Jujuba* is stated by Bosisto (*A. J. P.*, 1886) to be one of the main sources of stick-lac, from which shellac is manufactured.

Zygadenus.—This is a liliaceous genus, found in the United States, some members of which are believed to be poisonous. H. S. Goodell affirms that he has seen violent convulsions produced by the juice of *Z. venenosus*, Watson. According to Watson, among the northern tribes of Indians the bulb of this species is said to be very poisonous, and is known as the *Death Camass*.

Zymoidin.—A powder said to be composed of zinc oxide, bismuth oxide, aluminum oxide, iodine, boric acid, carbolic acid, gallic acid, salicylic acid, quinine, and other ingredients. It is used as an antiseptic and dusting powder.

PART III

SECTION I

In this division are included the subjects formerly embraced in the Appendix of this work, with the addition of the official tests and various tables, some of which are introduced for the first time in this Dispensatory, and the National Formulary in abstract.

Tests, Reagents, Test Solutions, and Volumetric Solutions. U. S. P. Eighth Decennial Revision.

The constant reference to tests in the previous pages, and the adoption of volumetric test solutions in the U. S. Pharmacopœias of 1880 and 1890, and the British Pharmacopœia (1898), necessitate the insertion of the official reagents and solutions used in the quantitative and qualitative tests. Great care should be used, in preparing these tests and selecting the reagents, to see that they come fully up to the official requirements, as the whole value of the test depends upon the purity of the reagent and the accuracy with which the solution has been made.

INTRODUCTORY.

Official Substances as Reagents.—Some official substances (chemicals, chemical solutions, etc.) are sufficiently pure to be used as reagents, if they comply with the tests of purity prescribed by the Pharmacopœia. Latin official names are not used as titles in the following list, the English name being preferred. In the case of non-official substances, the presence of certain impurities, though immaterial for their use as medicines, renders their employment as reagents unsuitable. Whenever a greater degree of purity is required than is provided for by the text of the Pharmacopœia, it will be specially mentioned in the following lists.

Abbreviations and Signs Used :

T.S. = Test Solution.

V.S. = Volumetric Solution.

$\frac{N}{1}$ = Normal (see under "Volumetric Solutions," page 1715).

$\frac{N}{2}$ = Half-normal ; $\frac{N}{10}$ = Tenth-normal ; $\frac{N}{50}$ = Fiftieth-normal ; $\frac{N}{100}$ = Hundredth-normal.

$\frac{2N}{1}$ = Double-normal (sometimes written : 2N).

Keeping of Reagents.—Reagents should be kept in bottles made of glass free from lead and arsenic, and not subject to corrosion by acids and alkalis.

The bottles should be closed by well-ground glass or rubber stoppers. Ground glass stoppers of bottles containing alkali hydroxides, ammonium sulphide, ammonia water, and other substances of alkaline reaction rapidly attacking ground glass surfaces, should be coated with a thin film of petrolatum.

Reagents easily affected by light, such as hydrogen sulphide T.S., ammonium sulphide T.S., chlorine water, silver nitrate T.S., etc., should be kept in bottles made of dark amber-colored glass.

NOTE.—As some of the following test solutions are in certain cases directed to be used in definite quantities in place of the regular volumetric solutions, it is important that they should always be prepared of the exact strength prescribed.

TESTS, REAGENTS, AND TEST SOLUTIONS.

NOTE.—The reagents are arranged in alphabetical order. The test solutions are usually mentioned in connection with the principal chemical or other substance from which they are prepared. The volumetric solutions will be found on page 1715.

Whenever water is required or mentioned as a solvent in the tests given in the Pharmacopœia, or in the preparation of any reagent, it is understood that distilled water shall be used.

1. Absolute Alcohol.—Ethyl Alcohol, C_2H_5OH .—Use the official absolute alcohol [*Alcohol Absolutum*, U. S. P.], which should be neutral to litmus T.S.

2. Acetic Acid, $HC_2H_3O_2$.—Use the official acetic acid [*Acidum Aceticum*, U. S. P.].

3. Albumin Test Solution.—Carefully separate the white of a hen's egg (which should be fresh) from the yolk, shake it thoroughly with 100 Cc. of water, and filter. This solution should be freshly made when required.

4. Alcohol.—Ethyl Alcohol, C_2H_5OH .—Use the official alcohol [*Alcohol*, U. S. P.]. Alcohol of lower strength is prepared as follows :

Alcohol, 90 per cent.—Mix 51 Cc. of alcohol [*Alcohol*, U. S. P.] with 3 Cc. of distilled water. The specific gravity of the mixture should be 0.826 at 25° C. (77° F.), corresponding to 90 per cent., by volume, of absolute alcohol.

5. Alcohol, 80 per cent.—Mix 45.5 Cc. of alcohol [*Alcohol*, U. S. P.] with 9.5 Cc. of distilled water. The specific gravity of the mixture should be 0.856 at 25° C. (77° F.), corresponding to 80 per cent., by volume, of absolute alcohol.

6. Alcohol, 70 per cent.—Mix 38.6 Cc. of alcohol [*Alcohol*, U. S. P.] with 15 Cc. of distilled water. The specific gravity of the mixture should be 0.882 at 25° C. (77° F.), corresponding to 70 per cent., by volume, of absolute alcohol.

7. Ammonia Water, NH_4OH .—Use the official ammonia water [*Aqua Ammoniae*, U. S. P.].

8. Ammonium Carbonate Test Solution.—Dissolve 20 Gm. of ammonium carbonate, NH_4HCO_3 . $\text{NH}_4\text{NH}_2\text{CO}_2$ [*Ammonii Carbonas*, U. S. P.], in a mixture of 20 Cc. of ammonia water and 70 Cc. of water, and add sufficient water to measure 100 Cc.

9. Ammonium Chloride Test Solution.—Dissolve 10 Gm. of ammonium chloride, NH_4Cl [*Ammonii Chloridum*, U. S. P.], in sufficient water to measure 100 Cc.

10. Ammonium Molybdate Test Solution.—Dissolve 15 Gm. of finely powdered ammonium molybdate, $(\text{NH}_4)_6\text{Mo}_7\text{O}_{24} + 4\text{H}_2\text{O}$, in 100 Cc. of distilled water, adding sufficient ammonia water, if necessary, to effect solution. Then gradually pour the liquid into 100 Cc. of nitric acid (sp. gr. 1.403 at 25° C. [77° F.]). The resulting solution, after being subjected to gentle heat for about two hours, should be decanted from any yellow sediment which may be deposited.

Alternative Method.

Solution No. 1.

Molybdic Acid, H_2MoO_4	10 Gm.
Ammonia Water (10 per cent.)	42 Cc.

Solution No. 2.

Nitric Acid (sp. gr. 1.403),	63 Cc.
Water, of each	

Pour Solution No. 1 into Solution No. 2 gradually, shaking repeatedly. After being subjected to a gentle heat for about two hours, the solution should be decanted from any yellow sediment which may be deposited.

Preserve the test solution in the dark, and, if a sediment should form in it after some days, carefully decant the clear solution from it.

11. Ammonium Oxalate Test Solution.—Dissolve 4 Gm. of pure crystallized ammonium oxalate, $(\text{NH}_4)_2\text{C}_2\text{O}_4 + \text{H}_2\text{O}$, in sufficient water to measure 100 Cc. Or, dissolve 4 Gm. of pure oxalic acid (see No. 73) in 100 Cc. of water, add 15 Cc. of ammonia water, boil to expel excess of ammonia, and dilute with water to 113 Cc.

On evaporating a portion of the test solution, and igniting the residue, it should be completely volatilized (absence of *fixed impurities*). The precipitate produced by the addition of silver nitrate T.S., or by barium chloride T.S., should dissolve without residue upon the addition of nitric acid (absence of *chlorides and sulphates*).

12. Ammonium Sulphate, $(\text{NH}_4)_2\text{SO}_4$.—This salt should respond to the following tests of purity: Three grammes should leave no appreciable residue upon ignition (absence of *fixed impurities*). The aqueous solution of the salt (1 in 10) should not respond to the Time-Limit Test for Heavy Metals (see No. 121). Another portion of this solution should not become turbid upon the addition of nitric acid and silver nitrate T.S. (absence of *chlorides*). Another portion of this solution should not be colored red upon the addition of 2 drops of hydrochloric acid and 1 drop of ferric chloride T.S. (absence of *sulphocyanate*). This salt may be prepared by neutralizing pure sulphuric acid, which has been diluted with an equal volume of water, with ammonia water, evaporating and crystallizing. During the evaporation, the solution should be tested from time to time with litmus paper, adding more ammonia if necessary to keep the liquid alkaline.

13. Ammonium Sulphide Test Solution.—Saturate 3 parts of pure ammonia water with hydrogen sulphide, prepared as directed (No. 47), and add to the solution (which now contains ammonium hydrogen sulphide, NH_4HS) 2 parts of ammonia water, which converts the greater portion of the ammonium hydrogen sulphide into ammonium sulphide, $(\text{NH}_4)_2\text{S}$. The solution should be perfectly clear and colorless, and should leave no residue on evaporation. It should not be rendered turbid either by magnesium sulphate T.S. (absence of *free ammonia*), or by calcium chloride T.S. (absence of *ammonium carbonate*). It should be protected against air and light by being kept in small, dark amber-colored bottles, in a cool, dark place. As soon as a notable deposit of sulphur has made its appearance in the solution, it should be rejected.

Ammonium polysulphide test solution is occasionally required. It is a yellow liquid, made by dissolving a small quantity of pure sulphur in the preceding colorless ammonium sulphide test solution.

14. Amyl Alcohol, $\text{C}_5\text{H}_{11}\text{OH}$.—A colorless, oily liquid having a penetrating characteristic odor, boiling at 131° C. (267.8° F.); soluble in 40 parts of water at 25° C. (77° F.); miscible with alcohol, ether, chloroform, carbon disulphide, petroleum benzin, benzene, and fixed and volatile oils.

15. Aniline (Phenylamine), $\text{C}_6\text{H}_5\text{NH}_2$.—When freshly distilled, aniline is a colorless, strongly refractive, oily liquid having a peculiar aromatic odor and a pungent, burning taste. Upon exposure to the light and air, it rapidly assumes a reddish-brown color. Specific gravity 1.0214 at 25° C. (77° F.). Aniline should distil over completely between 183° and 184° C. (361.4° and 363.2° F.). It is soluble in alcohol, ether, and the fixed and volatile oils. With acids, it forms soluble crystalline salts. When added to a solution of calcium or sodium hypochlorite a blue or purple color is produced.

16. Arsenic Test, Bettendorf's.—To a solution of the prescribed quantity of the substance to be tested in 5 Cc. of pure concentrated hydrochloric acid contained in a clean test-tube, 5 Cc. of a saturated solution of freshly prepared stannous chloride in pure concentrated hydrochloric acid (see No. 46) are added, and, after being heated for fifteen minutes while immersed in a bath of boiling water, the tube is allowed to stand for one hour. If arsenic be present in non-permissible amount, a brownish tint will become manifest when the tube is placed over a white surface and the solution viewed from above, comparison being made with a mixture of 5 Cc. each of pure concentrated hydrochloric acid and a saturated solution of stannous chloride, prepared under like conditions.

NOTE.—It is absolutely necessary that the solution of stannous chloride be freshly prepared, and that sulphates, sulphites, sulphides, and salts of mercury, gold, and selenium be absent from the reagents and the chemicals being tested.

17. Arsenic Test, Modified Gutzeit's.—The efficiency of this test depends upon a strict adherence to the conditions described below.

REAGENTS.

Zinc.—This should be in a granulated or fine mossy condition and free from arsenic, sulphur, and phosphorus, and should not contain more than 0.05 per cent. of iron. It should otherwise respond to all the tests given under Zinc [*Zincum*, U. S. P.].

Hydrochloric Acid (8 per cent.).—Mix 22.5 Cc. of hydrochloric acid [*Acidum Hydrochloricum*, U. S. P.] with water sufficient to measure 100 Cc.

Mercuric Chloride Test-Paper.—By means of a glass rod, transfer a drop of a saturated alcoholic solution of mercuric chloride to the centre of a piece of white filter-paper (preferably the kind used for quantitative analysis) of about 4 Cm. diameter; after drying, this paper is to be twice successively moistened with the reagent and dried. It is not necessary to moisten the paper with alcohol or the reagent while using it.

Lead Acetate Test-Gauze.—A piece of cheese cloth, about 1 decimeter square, when required for use, is thoroughly impregnated with lead acetate T.S., and the excess of fluid removed by pressure.

TEST-FLASK.

Select a flask of the capacity of about 60 to 75 Cc., with a neck of about 5 to 6 Cm. in length, and about 1 Cm. in diameter.

PREPARATION OF THE CHEMICAL TO BE TESTED.

To 5 Cc. of the aqueous solution of the chemical (1 in 10) or to a solution in 5 Cc. of water of the residue remaining after undergoing special treatment, 1 Cc. of a mixture of equal volumes of sulphuric acid and water is added, followed by 10 Cc. of a freshly prepared saturated solution of sulphurous acid. This liquid, contained in a small beaker, is heated upon a bath of boiling water until it is free from excess of sulphurous acid and has been reduced to 5 Cc. in volume.

THE TEST.

Before applying this test for the presence of arsenic in chemicals, in order to establish the freedom of the reagents from arsenic, sulphur, and phosphorus, or any interfering contaminations, a preliminary blank test should be made as follows: Into the flask are introduced 2 Gm. of zinc, 20 Cc. of the hydrochloric acid (see above), and 5 Cc. of water, and into the lower end of the neck of the flask is inserted a small wad of clean dry gauze, and then the lead acetate test-gauze, pressed with sufficient firmness to retain its place. About 1 Cm. space should be allowed above the gauze; the lip of the flask, after careful cleansing, is securely covered by folding over it the mercuric chloride test-paper. The reaction is allowed to proceed until the greater portion of the zinc has dissolved, which may require from one-half to two hours, when, if no trace of a yellow to orange-colored deposit is distinguishable upon the inner surface of the test-paper cap, the reagents are proved to be sufficiently pure, and a direct test may be applied at once. If a black stain is produced, sulphur compounds are present in the zinc or reagents, and this indicates unfitness for use. While the blank test is being carried out, another flask should be charged in a like manner with 2 Gm. of zinc and 20 Cc. of the hydrochloric acid (see above), followed by the 5 Cc. of the solution of the chemical (1 in 10) to be tested, which has undergone reduction as directed (under *Preparation of the Chemical to be tested*); the wad of clean dry gauze followed by the lead acetate test-gauze is then introduced, and after cleansing the lip of the flask the mercuric chloride cap is folded over the top. After the evolution of hydrogen has continued for at least one-half hour, and most of the zinc has dissolved, the inner side of the mercuric chloride test-cap is examined to detect the presence of a yellow stain.

The presence of arsenic much in excess of the permissible limit (1 in 100,000) is manifested by the formation of a distinct yellow to orange spot, according to the quantity present. Antimony produces a dark gray to brownish-black coloration. The production of a black stain indicates the presence of sulphur compounds (as sulphurous acid or sulphides), also possibly antimony. If the former be present, a simultaneous blackening of the lead acetate gauze will be observed. If such be the case, the operation, as directed under *Preparation of the Chemical to be tested*, must be repeated upon a fresh portion of the sample, using greater precautions for the complete removal of the sulphurous acid.

In testing such phosphorus compounds as hypophosphorous acid and the hypophosphites, special care should be observed to completely oxidize the sample as directed, otherwise a yellow stain, similar to that caused by arsenic, may be produced through the evolution of hydrogen phosphide.

Compounds containing antimony are tested for arsenic by Bettendorf's Test.

18. Barium Carbonate.—Purified barium carbonate, BaCO_3 , is prepared by dissolving 12 parts of purified, crystallized barium chloride in 30 parts of boiling water, then adding 5 parts of ammonium carbonate, followed by 5 parts of ammonia water; finally washing the precipitate thoroughly and drying.

19. Barium Chloride Test Solution.—Prepared from purified, crystallized barium chloride, $\text{BaCl}_2 + 2\text{H}_2\text{O}$. The aqueous solution of the salt should be perfectly neutral and should not respond to

the Time-Limit Test for Heavy Metals (see No. 121). The aqueous solution, after being precipitated by diluted sulphuric acid in slight excess, yields a filtrate which should not leave any permanent residue when evaporated and heated on platinum-foil (absence of *other fixed bases*). Diluted alcohol, after remaining in contact with it for several hours, should, upon ignition, show a pure yellowish-green flame free from red (absence of *traces of strontium*). To prepare the *test solution*, dissolve 10 Gm. of the salt in sufficient water to measure 100 Cc.

20. Barium Hydroxide Test Solution.—A saturated solution of crystallized barium hydroxide, $\text{Ba}(\text{OH})_2 + 8\text{H}_2\text{O}$, in water. This solution rapidly absorbs carbon dioxide from the air. It should be freshly prepared when required for use.

21. Barium Nitrate Test Solution.—Prepared from pure barium nitrate, $\text{Ba}(\text{NO}_3)_2$. This salt should respond to the same tests as barium chloride (see No. 19). In addition, its aqueous solution, when slightly acidulated with nitric acid, should not be rendered turbid by silver nitrate T.S. (absence of *chloride*). To prepare the *test solution*, dissolve 10 Gm. of the salt in sufficient water to make 100 Cc.

22. Benzin, or Petroleum Benzin.—Use the official purified petroleum benzin [*Benzinum Purificatum*, U. S. P.].

23. Benzene, or Benzole.—Benzene, C_6H_6 , is a colorless, transparent liquid of a peculiar, aromatic odor, sp. gr. 0.871 at 25°C . (77°F .), congealing at 5.2°C . (41.3°F .), and boiling at 80.4°C . (176.7°F .). It is insoluble in water, but soluble in 4 parts of alcohol, and in ether. When equal volumes of benzene and concentrated sulphuric acid are mixed, the latter should not become colored. On shaking 2 Cc. of benzene with 0.5 Cc. of sulphuric acid and 1 drop of fuming nitric acid, no green or blue tint should be produced (absence of *thiophene*).

24. Brazil-Wood Test Solution.—See under *Indicators* (No. 125).

25. Bromine Test Solution (Bromine Water).—An aqueous solution of bromine, Br [*Bromum*, U. S. P.], prepared by dissolving 1 Cc. of bromine in sufficient water to measure 100 Cc.

26. Calcium Chloride Test Solution.—Dissolve 10 Gm. of crystallized calcium chloride, $\text{CaCl}_2 + 6\text{H}_2\text{O}$, in sufficient water to measure 100 Cc.

27. Calcium Hydroxide Test Solution (Lime Water), $\text{Ca}(\text{OH})_2$.—Use the official lime water [*Liquor Calcis*, U. S. P.].

28. Calcium Sulphate Test Solution.—Introduce pulverized transparent crystals of native gypsum (selenite), $\text{CaSO}_4 + 2\text{H}_2\text{O}$, into a bottle nearly filled with water, agitate at intervals for twelve hours, and decant the clear, saturated solution when required. One part of gypsum requires, at 25°C . (77°F .), 378 parts of water for solution.

29. Carbon Disulphide, CS_2 .—Use the official carbon disulphide [*Carbonei Disulphidum*, U. S. P.].

30. Chlorine Test Solution (Chlorine Water).—Use the official chlorine water [*Liquor Chlori Compositus*, U. S. P.]. Since it deteriorates by keeping, it should be freshly prepared when required for use.

31. Chloroform, CHCl_3 .—Use the official chloroform [*Chloroformum*, U. S. P.]. It should be strictly neutral to moistened litmus paper.

32. Cobaltous Nitrate Test Solution.—The crystallized commercial salt, $\text{Co}(\text{NO}_3)_2 + 6\text{H}_2\text{O}$, is sufficiently pure, if, after it is dissolved in water, and the cobalt completely precipitated by ammonium sulphide T.S., the filtrate leaves no residue after evaporating and igniting. To prepare the *test solution*, dissolve 1 Gm. of the salt in 10 Cc. of water.

33. Cochineal Test Solution.—See under *Indicators* (No. 126).

34. Copper, Metallic, Cu, in the form of wire, foil, or turnings.

35. Cupric Ammonium Sulphate Test Solution.—A solution of cupri-tetrammonium sulphate, $\text{CuSO}_4 + 4\text{NH}_3 + \text{H}_2\text{O}$. To copper sulphate T.S. add ammonia water, until the precipitate first formed is nearly, but not completely, redissolved; then filter. This solution should be freshly made when required.

36. Cupric Sulphate Test Solution.—Dissolve 10 Gm. of cupric sulphate, $\text{CuSO}_4 + 5\text{H}_2\text{O}$ [*Cupri Sulphas*, U. S. P.], in sufficient water to measure 100 Cc.

37. Cupric Tartrate Test Solution.—See *Volumetric Solutions* (No. 133).

38. Diphenylamine Test Solution.—Prepared from diphenylamine, $(\text{C}_6\text{H}_5)_2\text{NH}$, which is in the form of grayish-white or colorless crystals, of a peculiar, aromatic odor, melting at 54°C . (129.2°F .), slightly soluble in water, more soluble in acids. It is used either in the dry state, or in solution in diluted sulphuric acid, as a test for nitric acid (in sulphuric acid, water, etc.), or for chlorine (in hydrochloric acid). To test a solution for the presence of nitric acid, a small portion of it is mixed with 1 or 2 drops of diphenylamine T.S., and then concentrated sulphuric acid, free from compounds of nitrogen, is poured in so as to form a layer beneath the solution. The presence of nitric acid is shown by a deep blue color at the zone of contact. A similar reaction is also produced by the presence of hypochlorites, chlorates, chromium trioxide, ferric salts, and similar oxidizing agents. The *test solution* is prepared by dissolving 0.1 Gm. of diphenylamine in 50 Cc. of sulphuric acid. The solution should be colorless.

39. Ether, $(\text{C}_2\text{H}_5)_2\text{O}$.—Use the official ether [*Ether*, U. S. P.]. It should be strictly neutral to moistened litmus paper.

40. Ferric Ammonium Sulphate Test Solution.—Dissolve 10 Gm. of ferric ammonium sulphate, $\text{FeNH}_4(\text{SO}_4)_2 + 12\text{H}_2\text{O}$ [*Ferri et Ammonii Sulphas*, U. S. P.], in sufficient water to measure 100 Cc.

41. Ferric Chloride Test Solution.—Dissolve 10 Gm. of ferric chloride [*Ferri Chloridum*, U. S. P.] in sufficient water to measure 100 Cc.

42. Ferrous Sulphate Test Solution.—Dissolve a clear crystal of ferrous sulphate, $\text{FeSO}_4 + 7\text{H}_2\text{O}$ [*Ferri Sulphas*, U. S. P.], in about 10 parts of water which has been previously boiled to expel air. This solution should be freshly prepared immediately before use.

43. Ferrous Sulphide, FeS.—A heavy solid, in the form of black or brownish-black irregular masses, or fused into sticks, soluble in diluted sulphuric or diluted hydrochloric acid, with copious evolution of hydrogen sulphide.

44. Gelatin Test Solution.—Dissolve 1 Gm. of purified gelatin [*Gelatinum*, U. S. P.] in 50 Cc. of water, with the aid of a gentle heat, and filter if necessary. This solution should be freshly made when wanted for use.

45. Gold Chloride Test Solution.—The commercial gold chloride, usually prepared by dissolving gold in nitro-hydrochloric acid and carefully evaporating to dryness, consists chiefly of chlorauric acid, $\text{HAuCl}_4 + 4\text{H}_2\text{O}$, which is converted into neutral auric chloride, AuCl_3 , by fusing it at a temperature not exceeding 150°C . (302°F .), moistening the residue (now consisting of auric and aurous chloride) with enough hot water to produce a syrupy liquid (whereby the aurous chloride is decomposed into auric chloride and metallic gold), and then pouring off the clear liquid from the precipitate. To prepare the test solution, mix the liquid finally obtained in the before-mentioned process with 20 volumes of water. Or, dissolve 1 Gm. of dry auric chloride in 30 Cc. of water.

46. Hydrochloric Acid, Pure, for Tests, HCl.—In addition to the tests prescribed for this acid [*Acidum Hydrochloricum*, U. S. P.], it is required to conform to the following more rigorous tests, before it can be employed as a reagent: The addition of 1 Cc. of barium chloride T.S. to 1 Cc. of the acid diluted with 9 Cc. of water should cause no turbidity within twenty-four hours (absence of sulphuric acid). A crystal of diphenylamine dropped into the acid should not turn blue (absence of free chlorine).

47. Hydrogen Sulphide, H_2S .—A gas generated by treating ferrous sulphide with diluted sulphuric acid, and washing the gas as directed under the Test Solution (No. 48).

48. Hydrogen Sulphide Test Solution (Hydrosulphuric Acid).—A saturated, aqueous solution of hydrogen sulphide. To prepare about 1000 Cc. of the solution, treat 20 Gm. of ferrous sulphide, in a suitable apparatus, with a mixture of 20 Cc. of sulphuric acid (U. S. P.), and 250 Cc. of water, pass the gas through a drying-tube filled with granulated calcium chloride, then from this through a tube of about 8 millimeters diameter and 40 centimeters in length, which contains about 5 Gm. of coarsely pulverized iodine mixed with spun glass (glass wool), and finally through a wash-bottle which contains a small quantity of potassium iodide T.S. The gas thus purified is conducted nearly to the bottom of a bottle of the capacity of about 1500 Cc., containing 1000 Cc. of cold water. The bottle should be shaken occasionally to facilitate the solution of the gas. When it is no longer absorbed, transfer the solution to small, dark amber-colored bottles, to be filled nearly to the top; pass a stream of hydrogen sulphide for a few minutes through each, and then at once stopper them tightly, and preserve them afterwards in a cool and dark place. Before any of the solution is used, it should be ascertained that it retains a strong odor of hydrogen sulphide, and that, when it is added to an equal volume of ferric chloride T.S., a copious precipitate of sulphur is formed at once.

49. Indicators.—See special list, page 1714.

50. Indigo Test Solution.—Dissolve 1 Gm. of commercial indigo-carmin, which is the sodium or potassium salt of indigo-disulphonic acid, $\text{H}_2\text{C}_8\text{H}_6\text{N}_2\text{O}_2(\text{SO}_3)_2$, in 150 Cc. of water.

51. Iodine Absorption Value of Fats and Oils.—The iodine value or number of a fat or an oil is a figure which indicates the percentage of iodine absorbed under certain conditions. It is determined as follows: To a solution of 0.3 Gm.¹ of the fat or oil in 10 Cc. of chloroform contained in a glass-stoppered bottle of 250 Cc. capacity, add 25 Cc. of a mixture of equal volumes of alcoholic iodine T.S., and alcoholic mercuric chloride T.S., both of which have been measured from a burette. After having been securely stoppered, the bottle is set aside in a cool place, protected from the light, for a period of four² hours. After this time, the mixture must still possess a brown color; if it does not, a further measured portion of the mixture of the two reagents should be added, and the mixture be again set aside. Finally, 20 Cc. of potassium iodide T.S. are added, followed by 50 Cc. of water, and tenth-normal sodium thiosulphate V.S. is then added in small successive portions, shaking thoroughly after each addition until the color of the mixture is discharged. The number of Cc. of the sodium thiosulphate V.S. consumed is noted. At the same time that this test is carried out, a blank experiment is made in which exactly the same quantities of chloroform, iodine T.S., and mercuric chloride T.S. are mixed, and after standing for four or more hours, the free iodine is estimated by titration with tenth-normal sodium thiosulphate V.S. as directed above. The number of Cc. of the thiosulphate V.S. consumed is noted, and from this is deducted the number of Cc. of the thiosulphate V.S. which was consumed in the test; the difference multiplied by 12.59, and this product divided by 3,³ gives the iodine value of the fat or oil.

52. Iodine Test Solution.—For preparing the ordinary test solution (as a reagent for starch, alcohol by iodoform test, etc.), iodine, I, fulfilling the requirements of the Pharmacopœia [*Iodum*, U. S. P.], is sufficiently pure. Dissolve 1 Gm. of iodine and 3 Gm. of potassium iodide in 50 Cc. of water.

For use in volumetric analysis, or in other cases where the ordinary impurities present in official iodine are objectionable, *Purified Iodine* must be employed (see No. 137).

53. Iodine Test Solution, Alcoholic.—Dissolve 25 Gm. of iodine [*Iodum*, U. S. P.] in 500 Cc. of alcohol. This solution is employed in the determination of the iodine absorption value of fats and oils (No. 51).

54. Iron, Metallic, Fe.—Bright and perfectly clean iron in the form of wire, sheet, filings, or electrolytically reduced to powder, according to the uses to be made of it. For making solutions of pure iron salts, fine, thin, bright wire (so-called florist's or piano wire) should be used. For detecting copper, bright pieces of sheet iron or steel knitting-needles are used.

¹ 0.15 to 0.2 Gm. for linseed oil and 0.8 Gm. for oil of theobroma and similar fats.

² Sixteen hours are required for accuracy in the case of linseed oil.

³ When the quantity of the fat or oil used is not 0.3 Gm., then the product is not divided by 3, but by the figure corresponding to the quantity taken; thus, for linseed oil, 0.15 Gm. would be divided by 1.5.

55. Lead Acetate Test Solution.—Dissolve 10 Gm. of clear, transparent crystals of lead acetate, $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2 + 3\text{H}_2\text{O}$ [*Plumbi Acetas*, U. S. P.], free from adhering lead carbonate, in sufficient water to measure 100 Cc. Preserve the solution in well-stoppered bottles.

56. Lead Acetate Test Solution, Basic.—Use the official solution of lead subacetate [*Liquor Plumbi Subacetatis*, U. S. P.].

57. Litmus Paper and Test Solution.—See under *Indicators* (No. 129).

58. Magnesia Mixture.—Dissolve 10 Gm. of magnesium sulphate, $\text{MgSO}_4 + 7\text{H}_2\text{O}$ [*Magnesi Sulphas*, U. S. P.], and 20 Gm. of ammonium chloride, NH_4Cl [*Ammonii Chloridum*, U. S. P.], in 80 Cc. of water, add 42 Cc. of ammonia water [*Aqua Ammoniae*, U. S. P.], set the mixture aside for a few days in a well-stoppered vessel, and filter. If not perfectly clear, the solution should always be filtered before using.

59. Magnesium Sulphate Test Solution.—Dissolve 10 Gm. of magnesium sulphate, $\text{MgSO}_4 + 7\text{H}_2\text{O}$ [*Magnesi Sulphas*, U. S. P.], in sufficient water to measure 100 Cc.

60. Mercuric Chloride Test Solution.—Dissolve 5 Gm. of mercuric chloride, HgCl_2 [*Hydrargyri Chloridum Corrosivum*, U. S. P.], in sufficient water to measure 100 Cc.

61. Mercuric Chloride Test Solution, Alcoholic.—Dissolve 30 Gm. of mercuric chloride, HgCl_2 [*Hydrargyri Chloridum Corrosivum*, U. S. P.], in 500 Cc. of alcohol. This solution is employed in the determination of the iodine absorption value of fats and oils (No. 51).

62. Mercuric Nitrate Test Solution, $\text{Hg}(\text{NO}_3)_2 + 4\text{H}_2\text{O}$.—Use the official solution of mercuric nitrate [*Liquor Hydrargyri Nitratis*, U. S. P.].

63. Mercuric Potassium Iodide Test Solution (Mayer's Reagent).—Dissolve 1.344 Gm. of mercuric chloride, HgCl_2 [*Hydrargyri Chloridum Corrosivum*, U. S. P.], in 60 Cc. of water, and 5 Gm. of potassium iodide [*Potassii Iodidum*, U. S. P.] in 10 Cc. of water. Mix the two solutions, and then add sufficient water to make the mixture measure 100 Cc.

64. Mercuric Potassium Iodide Test Solution, Alkaline (Nessler's Reagent).—Dissolve 10 Gm. of potassium iodide [*Potassii Iodidum*, U. S. P.] in 10 Cc. of water, and add gradually, in portions, a saturated aqueous solution of mercuric chloride [*Hydrargyri Chloridum Corrosivum*, U. S. P.], with constant agitation, until a slight red precipitate remains undissolved; to this mixture add 30 Gm. of potassium hydroxide [*Potassii Hydroxidum*, U. S. P.] and, when solution has taken place, 1 Cc. more of the saturated aqueous solution of mercuric chloride. Dilute this solution with water until it measures 200 Cc. Allow the precipitate to subside, and draw off the clear fluid.

NOTE.—2 Cc. of this reagent, when added to 50 Cc. of water containing 0.05 milligramme of ammonia, should produce at once a yellowish-brown coloration.

65. Mercurous Nitrate Test Solution.—Into a porcelain evaporating dish introduce 10 Gm. of pure mercury with 5 Cc. of pure nitric acid and 5 Cc. of distilled water, and set it aside for 24 hours in a cool, dark room. Separate and drain the crystals ($2\text{HgNO}_3 + \text{H}_2\text{O}$), and dissolve them in 100 Cc. of water. Preserve the solution in a dark, amber-colored bottle, into which a small quantity of mercury has been introduced.

66. Metals, Time-Limit Test for Heavy.—See No. 121.

67. Modified Gutzeit's Test.—See No. 17.

68. Methyl Alcohol, CH_3OH .—Rectified, purified wood-alcohol, having a specific gravity of about 0.812 at 25° C. (77° F.), and free from pyroligneous odor. Used for the identification of salicylic acid.

69. Methyl-Orange Test Solution.—See under *Indicators* (No. 130).

70. Naphthylamine Acetate Test Solution.—Boil 0.1 Gm. of alpha-naphthylamine acetate ($\text{C}_{10}\text{H}_7\text{NH}_2 \cdot \text{HC}_2\text{H}_3\text{O}_2$) in 20 Cc. of distilled water, filter through cotton, and mix the filtrate with 180 Cc. of diluted acetic acid (10 per cent. absolute acid). Only freshly distilled water should be employed in preparing this reagent, which must be kept in well-stoppered bottles, protected from the light.

71. Nitric Acid, HNO_3 .—Use the official nitric acid [*Acidum Nitricum*, U. S. P.].

72. Nitric Acid, Fuming.—Use the commercial red fuming acid, if it is of the specific gravity 1.437 at 25° C. (77° F.). It should be carefully kept in glass-stoppered bottles, in a cool place.

73. Oxalic Acid, Pure, $\text{H}_2\text{C}_2\text{O}_4 + 2\text{H}_2\text{O}$.—Pure Oxalic Acid is in the form of colorless, transparent, clino-rhombic crystals; 10 Gm. on ignition upon platinum foil should leave no residue. One part of the acid is completely soluble in 12 parts of water at 25° C. (77° F.). For the preparation of test and volumetric solutions, commercial oxalic acid should be purified as follows:

To 1 part of the Acid add 10 parts of cold water, and shake until the latter is saturated. Filter off the solution from the undissolved crystals, evaporate the filtrate to about three-fourths of its volume, and set it aside so that the fixed salts which it contains may crystallize out. Carefully decant the liquid from the crystals, concentrate it by evaporation, and set it aside to crystallize, stirring occasionally to prevent the formation of large crystals which might enclose moisture. Drain the crystals in a funnel, dry them carefully on blotting paper, and preserve them in well-stoppered bottles.

74. Oxalic Acid Test Solution.—Dissolve 10 Gm. of pure oxalic acid, $\text{H}_2\text{C}_2\text{O}_4 + 2\text{H}_2\text{O}$, in sufficient distilled water to measure 100 Cc.

75. Palladous Chloride Test Solution.—Dissolve 0.5 Gm. of palladous chloride, PdCl_2 , in sufficient water to measure 10 Cc. Preserve in a glass-stoppered bottle.

76. Phenolphthalein Test Solution.—See under *Indicators* (No. 131).

77. Picric Acid Test Solution.—Dissolve 1 Gm. of pure, distinctly crystalline picric acid (trinitrophenol), $\text{C}_6\text{H}_2(\text{NO}_3)_3\text{OH}$, in 100 Cc. of water, cool the solution and filter, if necessary.

78. Platonic Chloride Test Solution.—Dissolve 2.6 Gm. of chloroplatinic acid, $\text{H}_2\text{PtCl}_6 + 6\text{H}_2\text{O}$, in 20 Cc. of water. On evaporating a small portion of the solution to dryness and igniting the residue, pure metallic platinum should remain, which should yield nothing soluble in nitric acid.

79. Potassio-Mercuric Iodide Test Solution.—See No. 63.

80. Potassium Bitartrate, $\text{KHC}_4\text{H}_4\text{O}_6$.—The purification of potassium bitartrate [*Potassii Bitartras*, U. S. P.], to render it suitable for standardizing volumetric solutions of potassium and sodium hydroxide, is carried out as follows: To 100 Gm. of the salt contained in a beaker, is added a mixture of 85 Cc. of water and 25 Cc. of diluted hydrochloric acid; the covered beaker is then placed upon a bath of boiling water and the mixture digested, with occasional stirring, for three hours. After quickly cooling, the solution is drained off from the precipitate, which is washed by affusion and decantation with two successive portions of 100 Cc. each of water; after collecting the precipitate upon a plain filter, the washing with cold water is continued until the filtrate, after adding a few drops of nitric acid, ceases to become opalescent upon the addition of silver nitrate T.S. The precipitate of potassium bitartrate is then dissolved in the smallest possible volume of boiling water (about 1500 Cc.), filtered, and the filtrate, while being rapidly cooled, is constantly stirred. When the mixture is cold, the crystalline precipitate is collected upon a plain filter, washed with 300 Cc. of cold water, and, after thoroughly draining, dried at 120° C. (248° F.) until of constant weight. It should be kept in dry, securely stoppered bottles.

Purified potassium bitartrate is employed for standardizing normal and tenth-normal potassium or sodium hydroxide V.S.

81. Potassium Bromate, KBrO_3 .—White cubical crystals or granular crystalline powder, having a pungent, saline taste. Soluble in 15.5 parts of water at 25° C. (77° F.), and in 2 parts of boiling water; slightly soluble in alcohol. The aqueous solution has a neutral reaction, and upon the addition of diluted sulphuric acid no yellow color should at once be produced. When heated to 350° C. (662° F.), the salt undergoes decomposition with the evolution of oxygen. Potassium Bromate should not be triturated or heated with organic or easily oxidizable substances. The addition of nitric acid or sulphuric acid to the salt causes decomposition with the evolution of bromine. If 0.1 Gm. of Potassium Bromate, dried at 100° C. (212° F.), and 2 Gm. of potassium iodide be dissolved in about 25 Cc. of water contained in a glass-stoppered bottle (of about 100 Cc. capacity), and, after the addition of 5 Cc. of hydrochloric acid, the bottle be securely stoppered and set aside for ten minutes, not less than 36.1 Cc. of tenth-normal sodium thiosulphate V.S. should be required to discharge the color, corresponding to 99.8 per cent. of pure Potassium Bromate.

82. Potassium Carbonate Test Solution.—Dissolve 10 Gm. of anhydrous potassium carbonate, K_2CO_3 , prepared by heating potassium carbonate [*Potassii Carbonas*, U. S. P.] to 130° C. (266° F.), in sufficient water to measure 100 Cc.

83. Potassium Chromate Test Solution.—Dissolve 10 Gm. of yellow potassium chromate, K_2CrO_4 , in sufficient water to measure 100 Cc. On adding silver nitrate T.S. to a few drops of the solution diluted with a little distilled water, a red precipitate is produced which should be completely soluble in nitric acid (absence of *chloride*). Another portion of the solution, mixed with an equal volume of diluted hydrochloric acid, should yield no precipitate with barium chloride T.S. (absence of *sulphate*). Another portion of the solution should not become turbid upon the addition of ammonia water or ammonium oxalate T.S. (absence of *alkaline earths*). A solution of 0.1 Gm. of the salt in 20 Cc. of water should not become red upon the addition of a few drops of phenolphthalein T.S. (limit of *free alkalis*).

84. Potassium Cyanide Test Solution.—Dissolve 1 Gm. of potassium cyanide, KCN [*Potassii Cyanidum*, U. S. P.], in sufficient water to measure 10 Cc. This solution should be freshly prepared when required.

85. Potassium Dichromate, Pure, $\text{K}_2\text{Cr}_2\text{O}_7$.—In addition to the tests prescribed for this salt in the text of the Pharmacopœia, it is required to conform to more rigorous tests before it can be used in the preparation of the tenth-normal volumetric solution. In a solution of 0.5 Gm. of the salt in 10 Cc. of water rendered acid by 0.5 Cc. of nitric acid, no turbidity should be produced by barium chloride T.S. (absence of *sulphates*).

To 10 Cc. of the aqueous solution of the salt (1 in 20), the addition of 1 Cc. of ammonia water, followed by 1 Cc. of ammonium oxalate T.S., should produce no turbidity (absence of *calcium*).

If to a solution of 0.5 Gm. of the salt in 20 Cc. of water, sufficient sulphurous acid be added to impart a strong odor of the reagent, and the mixture be boiled for about three minutes and cooled, the addition of 1 Cc. of nitric acid and a few drops of silver nitrate V.S. should produce no turbidity (absence of *chlorides*).

Potassium dichromate which fails to meet all of the above requirements may be purified by recrystallization, the hot, saturated aqueous solution of the salt being rapidly cooled with agitation. The granular crystals, after being collected on a plain filter and washed with sufficient cold water to remove the mother liquor, are thoroughly drained and then dried at 120° C. (248° F.). This recrystallization should be repeated until the salt responds to all of the above tests for purity.

86. Potassium Dichromate Test Solution.—Dissolve 10 Gm. of pure potassium dichromate (No. 85) in sufficient water to measure 100 Cc.

87. Potassium Ferricyanide Test Solution.—Dissolve 1 part of potassium ferricyanide, $\text{K}_3\text{Fe}(\text{CN})_6$, in about 10 parts of water. This solution should be freshly made when required, as it undergoes decomposition with formation of ferrocyanide on standing. A freshly prepared aqueous solution, when mixed with some ferric chloride T.S. which has been well diluted with water, should show a brown tint, free from turbidity or a shade of green. Potassium Ferricyanide should respond to the tests for the absence of sulphates and chlorides as described under Potassium Ferrocyanide (No. 88).

88. Potassium Ferrocyanide, $\text{K}_4\text{Fe}(\text{CN})_6 + 3\text{H}_2\text{O}$.—In the form of large, soft, transparent, yellow, four-sided, monoclinic tabular crystals, odorless, and having a mild, saline taste. Slightly efflorescent on exposure to dry air.

Soluble in three parts of water at 25° C. (77° F.), and in 2 parts of boiling water; insoluble in alcohol. The aqueous solution is neutral to litmus paper. No effervescence should be caused by the addition of diluted sulphuric acid to a concentrated solution of the salt (absence of *carbonate*).

The aqueous solution (1 in 20), acidulated with hydrochloric acid, should, upon the addition of barium chloride T.S., remain clear (absence of *sulphate*). If a mixture of 0.5 Gm. of the salt with 1.5 Gm. of pure potassium nitrate and 0.5 Gm. of pure anhydrous sodium carbonate be heated to redness in a porcelain crucible, the residue dissolved in water, and the filtered solution supersaturated with nitric acid, no turbidity should be produced upon the addition of silver nitrate T.S. (absence of *chloride*). The precipitate produced in the aqueous solution, acidulated with nitric acid, by silver nitrate T.S. should be of a pure white color, without a tinge of red (absence of *ferricyanide*).

89. Potassium Ferrocyanide Test Solution.—Dissolve 10 Gm. of potassium ferrocyanide, $K_4Fe(CN)_6 + 3H_2O$, in sufficient water to measure 100 Cc.

90. Potassium Hydroxide Test Solution.—Use the official solution of potassium hydroxide, KOH [*Liquor Potassii Hydroxidii*, U. S. P.].

91. Potassium Hydroxide Test Solution, Alcoholic.—Use the half-normal alcoholic potassium hydroxide V.S. (Nos. 99 and 144).

92. Potassium Iodide Test Solution.—Dissolve 20 Gm. of potassium iodide, KI [*Potassii Iodidum*, U. S. P.], in sufficient water to measure 100 Cc., and keep the solution in dark amber-colored, well-stoppered bottles. The solution should be frequently renewed.

93. Potassium Nitrate, KNO_3 .—The dry salt [*Potassii Nitras*, U. S. P.], responding to the tests of purity required by the Pharmacopœia. It should also be free from chlorides and sulphates.

94. Potassium Permanganate Test Solution, $KMnO_4$.—Use No. 145.

95. Potassium Sulphate Test Solution.—Dissolve 1 Gm. of potassium sulphate, K_2SO_4 , in sufficient water to measure 100 Cc.

96. Potassium Sulphocyanate, KSCN.—Colorless, prismatic crystals, of cooling, saline taste, and hygroscopic in moist air. Readily soluble in less than its own weight of water; soluble in 10 parts of absolute alcohol.

The aqueous solution of the salt (1 in 20) should not become turbid within five minutes upon the addition of barium chloride T.S. (limit of *sulphate*).

The aqueous solution (1 in 20), after the addition of 1 Cc. of diluted hydrochloric acid, should remain colorless (absence of *iron*), and should not respond to the Time-Limit Test for Heavy Metals (No. 121).

97. Potassium Sulphocyanate Test Solution.—Use the tenth-normal volumetric solution (No. 146).

98. Resins, etc., Acid Number for.—Dissolve 1 Gm. of the resinous substance in alcohol, add a few drops of phenolphthalein T.S., and titrate with normal potassium hydroxide V.S.; the amount of potassium hydroxide consumed (expressed in milligrammes) is termed the Acid Number. The reaction is often more distinct if an excess of normal potassium hydroxide V.S. be used and the solution titrated back with normal acid V.S.

99. Saponification Value of Fats and Oils.—The determination of the saponification value is conducted as follows: Weigh out accurately, in a flask holding 150 to 200 Cc., 1.5 to 2 Gm. of the purified and filtered fat. Next run into the flask, with a burette, 25 Cc. of alcoholic potassium hydroxide T.S. (see No. 144). While exactly 25 Cc. is not indispensable, in comparative tests precisely the same amount must be used, allowing the burette to drain in exactly the same way in each test. Then place a small funnel in the flask and heat it on a water-bath containing boiling water, for half an hour, so that the alcohol is simmering, frequently imparting a rotatory motion to the contents of the flask. Then add 1 Cc. of phenolphthalein T.S., and titrate back the excess of potassium hydroxide with half-normal hydrochloric acid V.S. A blank test is made at the same time, using the alcoholic potassium hydroxide T.S. alone; the difference in the number of cubic centimeters of half-normal hydrochloric acid V.S. consumed by the blank test and the real test, multiplied by 27.87, and divided by the weight in grammes of the fat or oil, will give the saponification equivalent of the sample tested.

100. Silver Ammonium Nitrate Test Solution.—Dissolve 1 Gm. of silver nitrate, $AgNO_3$ [*Argenti Nitras*, U. S. P.], in 20 Cc. of water, and add ammonia water, drop by drop, until the precipitate first produced is almost, but not entirely, redissolved. Filter the solution, and preserve it in dark amber-colored and well-stoppered bottles.

101. Silver Nitrate Test Solution, $AgNO_3$.—For ordinary purposes, use the tenth-normal volumetric solution (see No. 147).

102. Silver Sulphate Test Solution.—Dissolve 1 Gm. of silver nitrate [*Argenti Nitras*, U. S. P.] in 0.5 Cc. of warm water, and add 1.5 Cc. of pure, concentrated sulphuric acid. On cooling, small transparent crystals of silver sulphate, Ag_2SO_4 , separate. Carefully pour off the acid liquid, wash the crystals repeatedly, by decantation, with cold water, transfer them to a bottle, add 100 Cc. of water, and agitate so as to produce a saturated solution. For use, decant a sufficient quantity of the latter.

103. Sodium Acetate Test Solution.—Dissolve 10 Gm. of sodium acetate, $NaC_2H_3O_2 + 3H_2O$ [*Sodii Acetas*, U. S. P.], in sufficient water to measure 100 Cc.

104. Sodium Bitartrate Test Solution, $NaHC_4H_4O_6 + H_2O$.—To a solution of 3.5 Gm. of tartaric acid [*Acidum Tartaricum*, U. S. P.] in about 80 Cc. of boiling water, add gradually, in small portions, monohydrated sodium carbonate [*Sodii Carbonas Monohydratus*, U. S. P.] until the solution has a neutral reaction; to this liquid is now added 3.5 Gm. of tartaric acid, and after filtering and cooling, sufficient water is added to the solution to measure 100 Cc. This solution should be freshly prepared when required.

105. Sodium Carbonate.—The monohydrated salt, $Na_2CO_3 + H_2O$, conforming to the tests prescribed by the Pharmacopœia [*Sodii Carbonas Monohydratus*], but absolutely free from chloride and sulphate.

106. Sodium Carbonate Test Solution.—Dissolve 10 Gm. of monohydrated sodium carbonate, $Na_2CO_3 + H_2O$ [*Sodii Carbonas Monohydratus*, U. S. P.], in sufficient water to measure 100 Cc.

107. Sodium Cobaltic Nitrite Test Solution. $\text{Co}_2(\text{NO}_2)_6.6\text{NaNO}_2 + \text{H}_2\text{O}$.—Dissolve 4 Gm. of cobaltous nitrate, $\text{Co}(\text{NO}_3)_2 + 6\text{H}_2\text{O}$, and 10 Gm. of sodium nitrite, NaNO_2 , in about 50 Cc. of water, add 2 Cc. of acetic acid [*Acidum Aceticum*, U. S. P.], and dilute with sufficient water to measure 100 Cc. A few drops of acetic acid should be added to the solution from time to time. The reagent should not be kept longer than three months.

108. Sodium Hydroxide Test Solution. NaOH .—Use the official solution of sodium hydroxide [*Liquor Sodii Hydroxidi*, U. S. P.].

109. Sodium Nitrite. NaNO_2 .—The purest commercial salt, either granulated or in the form of sticks, is sufficiently pure.

110. Sodium Nitroprusside Test Solution.—Dissolve 1 part of sodium nitroprusside, $\text{Na}_2\text{Fe}(\text{NO})(\text{CN})_5 + 2\text{H}_2\text{O}$, in 19 parts of water immediately before using.

111. Sodium Phosphate Test Solution.—Dissolve 10 Gm. of sodium phosphate, $\text{Na}_2\text{HPO}_4 + 12\text{H}_2\text{O}$ [*Sodii Phosphas*, U. S. P.], in sufficient water to measure 100 Cc.

112. Sodium Tartrate Test Solution. $\text{Na}_2\text{C}_4\text{H}_4\text{O}_6 + 2\text{H}_2\text{O}$.—To a solution of 6.5 Gm. of tartaric acid [*Acidum Tartaricum*, U. S. P.] in about 80 Cc. of boiling water, add gradually, in small portions, monohydrated sodium carbonate [*Sodii Carbonas Monohydratus*, U. S. P.] until the solution has a neutral reaction; after filtering and cooling, add sufficient water to measure 100 Cc. This solution should be freshly prepared when required.

113. Sodium Thiosulphate. $\text{Na}_2\text{S}_2\text{O}_3 + 5\text{H}_2\text{O}$.—In addition to the tests prescribed for this salt in the text of the Pharmacopœia [*Sodii Thiosulphas*], it is required to conform to the following more rigorous tests before it can be used in preparing the standard volumetric solution. If to a solution of the salt (1 in 20) in distilled water, iodine T.S. be added, drop by drop, until it retains a faint but permanent brown color, no turbidity should be produced upon the addition of barium chloride T.S. (absence of *sulphates and sulphites*). The addition of 1 drop of phenolphthalein T.S. to the aqueous solution of the salt (1 in 10) should produce not more than a very faint rose-tint (absence of *free alkalis*). The aqueous solution of the salt (1 in 20) should not become cloudy upon the addition of ammonium oxalate T.S. (absence of *calcium salts*).

114. Sodium Thiosulphate Test Solution.—Use the tenth-normal volumetric solution (No. 151).

115. Stannous Chloride Test Solution.—Heat pure tin (see No. 122), in the form of foil or granules, with concentrated hydrochloric acid, taking care that the metal be in excess. When the acid is saturated, crystals of stannous chloride, $\text{SnCl}_2 + 2\text{H}_2\text{O}$, begin to form. Remove and drain these, dissolve them in 10 parts of water, and preserve the solution in well-stoppered bottles, into each of which a fragment of pure tin, or a piece of pure tin-foil, has previously been introduced.

For Bettendorf's test (see No. 16), pure concentrated hydrochloric acid (which responds to the U. S. P. tests of purity) is saturated with the freshly prepared crystals.

116. Starch Test Solution.—Triturate 1 Gm. of starch [*Amylum*, U. S. P.] with 10 Cc. of cold water, and then add sufficient boiling water, with constant stirring, to make about 200 Cc. of a thin, translucent fluid. This solution should be freshly prepared and filtered when required for use.

117. Sulphanilic Acid Test Solution.—Dissolve 0.5 Gm. of sulphanilic acid, $\text{C}_6\text{H}_4(\text{NH}_2)(\text{SO}_3\text{H})$ (para-amidobenzenesulphonic acid), in 150 Cc. of diluted acetic acid (10 percent absolute acetic acid). Only freshly distilled water should be employed in preparing the diluted acetic acid.

This reagent should be kept in well-stoppered bottles.

118. Sulphuric Acid, Pure, for Tests. H_2SO_4 .—The sulphuric acid of the Pharmacopœia, which has a specific gravity of 1.826 at 25° C. (77° F.), will answer as a reagent for most purposes, provided it is of the required degree of purity. But when "concentrated" sulphuric acid is specially directed in a test, it is intended that the strongest obtainable pure acid, of a specific gravity of not less than 1.834 at 25° C. (77° F.), be employed.

In addition to the tests prescribed for this acid in the text of the Pharmacopœia, it is required to conform to the following more rigorous tests before it can be employed as a reagent. If 1 Cc. of diphenylamine T.S. (see No. 38) be carefully poured, as a separate layer, upon 5 Cc. of sulphuric acid, contained in a test-tube, no distinct blue color should appear in the zone of contact (absence of *nitric acid*).

119. Tannic Acid Test Solution.—Dissolve 1 Gm. of tannic acid, $\text{HC}_{14}\text{H}_9\text{O}_9$ [*Acidum Tannicum*, U. S. P.], in 1 Cc. of alcohol, and add sufficient water to measure 10 Cc.

120. Tartaric Acid Test Solution.—Dissolve 1 part of tartaric acid, $\text{H}_2\text{C}_4\text{H}_4\text{O}_6$ [*Acidum Tartaricum*, U. S. P.], in 3 parts of water. Since fungous growths rapidly destroy the solution of tartaric acid, it should be prepared only as wanted.

121. Time-Limit Test for Heavy Metals.—This test is to be used to detect the presence of undesirable metallic impurities in official chemical substances or their solutions; these should not respond affirmatively within the stated time.

Ten Cc. of a solution of the substance in distilled water (1 in 20), contained in a test-tube of about 40 Cc. capacity, is acidulated with 1 Cc. of diluted hydrochloric acid (unless otherwise directed), warmed to about 50° C. (122° F.), and an equal volume of freshly prepared hydrogen sulphide T.S. added, and the mixture allowed to stand, in the well-stoppered test-tube, in a warm place, at 35° C. (95° F.) for at least half an hour. At the end of this time any coloration or turbidity is carefully noted, ammonia water is added in excess, and the solution again examined for a coloration or turbidity.

Before the addition of the ammonia water, the mixture should still possess the odor of hydrogen sulphide; if not, it should be thoroughly saturated with the gas and again set aside for half an hour.

Any change in the color of the solution which is being tested should be noted by comparison with the same volume of the hydrogen sulphide T.S. (which has been likewise acidulated), when viewed by reflected light while held against a white surface.

Antimony yields, upon the addition of hydrogen sulphide T.S. to highly diluted solutions, a pale yellow to orange color, or, to more concentrated solutions, an orange precipitate, which is soluble in test

solutions of potassium hydroxide and ammonium sulphide, as well as in strong hydrochloric acid. The precipitate is insoluble in test solution of ammonium carbonate. The addition of ammonia water to the highly diluted hydrogen sulphide solution of antimony slightly intensifies the coloration.

Arsenic yields, upon the addition of hydrogen sulphide T.S. to highly diluted solutions, a pale yellow color, or, to more concentrated solutions, a yellow precipitate, which is soluble in test solutions of potassium hydroxide, ammonium sulphide, and ammonium carbonate, but is reprecipitated upon the addition of hydrochloric acid, insoluble in excess. The addition of ammonia water to the highly diluted hydrogen sulphide solution of arsenic slightly intensifies the yellow color.

Cadmium in very dilute solutions gives, with hydrogen sulphide T.S. or ammonium sulphide T.S., a pale yellow color; it yields in more concentrated solutions (not excessively acid) a yellow precipitate, which is insoluble in cold diluted hydrochloric acid, potassium hydroxide T.S., or ammonium sulphide T.S. (distinction from *arsenic*), and in solution of potassium cyanide. This precipitate is soluble in nitric and hydrochloric acids and in hot diluted hydrochloric and sulphuric acids.

Copper yields, upon the addition of hydrogen sulphide T.S. to highly diluted solutions, a pale brown color, or, to more concentrated solutions, a brownish-black precipitate, which is insoluble in diluted hydrochloric acid and test solution of potassium hydroxide, and is but very slightly soluble in test solution of ammonium sulphide. The precipitate is soluble in warm diluted nitric acid and also in solution of potassium or sodium cyanide. The addition of ammonia water to the highly diluted hydrogen sulphide solution containing copper slightly intensifies the coloration.

Iron.—Acidified solutions of ferrous iron do not react with hydrogen sulphide T.S., but yield a dark coloration or black precipitate with ammonium sulphide T.S., or upon the addition of ammonia water to the hydrogen sulphide mixture. This latter precipitate is soluble in cold diluted hydrochloric acid.

Acidified solutions of ferric iron yield a white turbidity or precipitate of sulphur upon the addition of hydrogen sulphide T.S., but a dark coloration or black precipitate with ammonium sulphide T.S., or upon the addition of ammonia water to the hydrogen sulphide mixture. This precipitate is readily soluble in acetic and inorganic acids.

Lead yields, upon the addition of hydrogen sulphide T.S. or ammonium sulphide T.S. to highly diluted solutions, a pale brown coloration, or, to more concentrated solutions, a black precipitate, which is insoluble in diluted hydrochloric acid, and also in test solutions of potassium hydroxide and ammonium sulphide.

Zinc yields, with ammonium sulphide T.S., and with hydrogen sulphide T.S., either in neutral solution, or after acidulation with acetic acid (in the absence of free mineral acids), a white turbidity in highly diluted solutions, but with concentrated solutions a white precipitate soluble in hydrochloric acid and insoluble in acetic acid.

122. Tin.—Pure metallic tin, Sn, in the granulated or mossy condition. Its solution in hydrochloric acid should give no precipitate with potassium sulphate T.S. (absence of *lead*), and, when tested by the Modified Gutzeit's Test (No. 17), replacing the zinc by tin, the diluted hydrochloric acid by hydrochloric acid U. S. P., and adding 1 drop of platonic chloride T.S., the mercuric chloride cap should not become colored within the time required for the solution of the metal (absence of *arsenic*).

123. Turmeric Paper and Tincture.—See under *Indicators* (No. 132).

124. Zinc.—Pure metallic zinc, Zn [*Zincum*, U. S. P.]. See also Modified Gutzeit's Test (No. 17).

INDICATORS FOR ACIDIMETRY, ALKALIMETRY, etc.

NOTE.—Each test solution used as *indicator* should be examined as soon as prepared, and afterwards from time to time, as to its neutrality. If necessary, it should be brought, by the cautious addition of highly diluted sulphuric acid, or of a very dilute solution of an alkali, to such a point that, when a few drops of it are added to 25 Cc. of water, a few drops of a hundredth-normal acid or alkali V.S., respectively, will distinctly develop the appropriate tints.

Since many of the colored test solutions are injured by exposure to light, it is best to preserve them in dark amber-colored vials. Papers prepared with them should be kept in dark bottles or paper boxes.

125. Brazil-Wood Test Solution.—Boil 50 Gm. of finely cut Brazil-wood [the heart-wood of *Peltophorum dubium* (Sprengel), Britton, Fam. *Leguminosæ*] with 100 Cc. of water during half an hour, replacing the water from time to time. Allow the mixture to cool, strain, wash the contents of the strainer with water until 100 Cc. of strained liquid are obtained, add 25 Cc. of alcohol, and filter. Care should be taken to exclude ammoniacal vapors while filtering. This solution is turned purplish-red by alkalis, and yellow by acids.

126. Cochineal Test Solution.—Macerate 1 Gm. of unbroken cochineal [*Coccus*, U. S. P.], during four days, with 20 Cc. of alcohol and 60 Cc. of water. Then filter. The color of this test solution is turned *violet* by alkalis, and *yellowish-red* by acids. Cochineal T.S. is useful in titrating alkaloids, inorganic acids, ammonia, the alkalis, and alkaline earths. The presence of salts of iron, alumina, or copper should be avoided. This indicator is useless for titrating organic acids.

127. Hematoxylin Test Solution.—Dissolve 0.2 Gm. of hematoxylin [a crystalline substance derived from *Hæmatoxylin*, U. S. P.] in 100 Cc. of alcohol. Use about 5 drops for each titration. This indicator assumes a *yellow* to *orange* color in acid solutions, and a *violet* to *purple* color in alkaline solutions. The titration is complete when the change in color remains permanent upon the addition of one drop of the volumetric solution after stirring the liquid.

128. Iodeosin Test Solution.—Dissolve 0.1 Gm. of iodeosin, $\text{C}_{40}\text{H}_{54}\text{I}_4\text{O}_5$ (*tetraiodofluorescein*), in 100 Cc. of alcohol. This indicator becomes *colorless* in acid solutions, changing to *pink* in alkaline solutions. Dilute the solution to be titrated in a 200 Cc. flask with distilled water to about 100 Cc., add 20 Cc. of ether and 5 drops of the iodeosin T.S., cork, and shake well. Then add the volumetric alkali solution gradually, shaking well after each addition. The titration is complete when the lower aqueous solution retains a faint *pink* color after shaking thoroughly. For assaying alkaloidal residues, dissolve

the latter in a measured excess of volumetric acid solution, and transfer the acid solution to a 200 Cc. flask, washing the container well with water until the contents of the flask measure about 100 Cc. Then proceed as above.

129. Litmus Paper and Test Solution.—Exhaust powdered litmus with three separate and successive portions (representing about 4 times its weight) of boiling alcohol (which removes the undesirable color erythrolitmin), each extraction lasting for about one hour. After draining off the alcohol, digest the residue with about an equal weight of cold water and filter. (This blue solution, which contains some alkali, after being acidulated, may be used to make red litmus paper.) Finally, extract the residue with about 5 times its weight of boiling water, and, after thoroughly cooling, filter. The addition of 1 drop of tenth-normal acid or alkali V.S. to 50 Cc. of water containing 5 drops of the indicator should produce a distinct change in color. Preserve the filtrate, as *test solution*, in wide-mouthed bottles stoppered with loose plugs of cotton so as to exclude dust but admit air. The blue color of litmus test solution is changed by acids to *red*, and this red color by the addition of alkalies is restored to *blue*.

Litmus Paper, Blue.—Impregnate with the test solution just described strips of white, unsized paper, free from wood-pulp, but not too porous, and dry them by suspending them on lines of clean twine, in an atmosphere free from acid or ammoniacal vapors.

Litmus Paper, Red.—Prepare this with the same kind of paper and in the same manner as described in the preceding paragraph. Add to the test solution used to impregnate the paper just sufficient of a highly diluted solution of hydrochloric acid to impart to it a faint red tint.

Neither blue nor red litmus paper should have a very intense color.

Preserve the test-paper in bottles, so as to exclude dust and acid or ammoniacal vapors.

130. Methyl-Orange Test Solution.—Dissolve 1 Gm. of methyl-orange, $\text{NaC}_{14}\text{H}_{14}\text{N}_3\text{SO}_3$ (the sodium or ammonium salt of dimethylamidoazobenzene sulphonic acid; also known as helianthin, tropaeolin D, or Poirrier's Orange 3 P), in 1000 Cc. of water. Add to it, carefully, with constant stirring, tenth-normal sulphuric acid V.S., in drops, until the liquid turns red and just ceases to be transparent. Then filter.

To distinguish methyl-orange from other orange colors of this class, which are unfit for use as indicators, it should respond to the following tests:

Methyl-orange should be completely soluble in distilled water, and the test solution should be of an orange-yellow color, free from a brownish tint. No precipitate should form in this solution upon the addition of an alkali.

The addition of hydrochloric acid to a hot, concentrated solution of methyl-orange should produce a crystalline precipitate, composed of lustrous plates having a violet reflection and free from brown tint.

The addition of calcium chloride or barium chloride T.S. should produce no precipitate.

A few drops of gold chloride T.S. should produce a red coloration, free from either a violet or green tint.

Excessive quantities of this indicator should be avoided in titrating; from 1 to 3 drops are sufficient for a volume of from 50 to 100 Cc., or just enough is added to impart a faint tint to the solution, which if neutral should change to a red or yellow respectively upon the addition of 2 drops of a tenth-normal acid or alkali V.S.

Methyl-orange is suitable for titrating inorganic acids, alkalies, alkali carbonates or bicarbonates, also certain alkaloids, as morphine and quinine. It is not to be employed in titrating organic acids, nor in alcoholic or boiling solutions.

This indicator gives a *yellow* color with alkalies and *red* with acids.

131. Phenolphthalein Test Solution.—Dissolve 1 Gm. of phenolphthalein ($\text{C}_{20}\text{H}_{14}\text{O}_4$) in 50 Cc. of alcohol and dilute to 100 Cc. with water. About 3 drops are sufficient for 50 Cc. of the solution to be titrated; it gives a *red* color with alkali hydroxides or carbonates, while acids render the solution *colorless*. Phenolphthalein may be employed in hot titrations. It is not suitable as an indicator for ammonia, but is largely used for organic acids, alkali hydroxides, and for carbonates and bicarbonates in boiling solutions.

Phenolphthalein Paper is prepared by impregnating white, unsized paper with the test solution and drying it.

132. Turmeric Tincture.—Digest any convenient quantity of ground turmeric root (from *Curcuma longa*, Linné, Fam. *Zingiberaceæ*) repeatedly with small quantities of water and discard the liquids. Then digest the dried residue for several days with six times its weight of alcohol, and filter.

Turmeric Paper.—Impregnate white, unsized paper with the tincture, and dry it. The tincture, as well as the paper, turns *brown* with alkalies, and the original *yellow* color is restored by acids, with the exception of boric acid, which, even in the presence of hydrochloric acid, turns the color to reddish-brown, and this is changed to bluish-black by ammonia.

VOLUMETRIC SOLUTIONS.

NOTE.—It is absolutely necessary that the measuring vessels employed in the operations of volumetric analysis, consisting of burettes, flasks, mixing cylinders, pipettes, etc., should agree among themselves accurately in their graduation at the standard temperature selected. It is immaterial what standard temperature has been selected for the graduation of the vessels.

All volumetric solutions must be prepared at the standard temperature of 25° C. (77° F.), and the solutions must be used in the titrations at a temperature not below 21° C. (69.8° F.), nor above 29° C. (84.2° F.).

All bottles in which volumetric solutions are to be kept, as well as the burettes or pipettes in which they are to be measured, should, prior to use, be thoroughly rinsed with distilled water, then with two or three small portions of the solution that they are to contain. When not in use, burettes should be kept filled with distilled water.

Normal volumetric solutions ($\frac{N}{1}$) are those which contain in one liter, in any stated reaction, the chemical equivalent of one gramme of hydrogen. If the molecule of the reagent is univalent, one liter

will contain the weight in grammes equal to the molecular weight of the reagent; if bivalent, a weight in grammes equal to one-half its molecular weight; if trivalent, a weight in grammes equal to one-third its molecular weight.

Thus, hydrochloric acid, $\text{HCl} = 36.18$, having but one H atom replaceable by a basic element, has 36.18 Gm. of absolute HCl in 1000 Cc. of the normal volumetric solution; while sulphuric acid, $\text{H}_2\text{SO}_4 = 97.35$, having two replaceable H atoms, contains only one-half this number, or 48.675 grammes of absolute H_2SO_4 in 1000 Cc. of its normal solution. Potassium hydroxide, $\text{KOH} = 55.74$, has but one K to replace one H in acids, hence its normal solution contains 55.74 grammes of pure KOH in one liter. Again, one molecule of potassium dichromate in oxidation liberates three atoms of oxygen which are capable of oxidizing six atoms of ferrous to ferric iron. Therefore, each molecule of the dichromate, yielding three atoms of oxygen, is equivalent to six atoms of hydrogen. Hence, the normal solution should contain $\frac{292.28}{6}$ or 48.713 Gm. in 1000 Cc. Two molecules of potassium permanganate, $2\text{KMnO}_4 = 313.96$, in oxidation, give off five atoms of O, which are equivalent to ten atoms of H; hence its normal solution should contain $\frac{313.96}{10}$ or 31.396 Gm. in 1000 Cc.

Solutions containing in 1000 Cc. one-tenth of the quantity of the active reagent in the normal solution are called tenth-normal ($\frac{N}{10}$); those containing one-hundredth, hundredth-normal ($\frac{N}{100}$); one-fiftieth, fiftieth-normal ($\frac{N}{50}$); those containing twice the amount, double-normal ($\frac{2N}{1}$); half the amount, half-normal ($\frac{N}{2}$).

Solutions containing quantities of the active reagent having no simple relation to the molecular weight are called empirical.

In the majority of the assays it has been directed that an integral quantity (1, 2, 5, or 10 Gm.) of the substance which is to be tested be weighed, dissolved in water, and made up to a definite volume, then an aliquot portion (representing the fractional weight of the substance required) is measured off for titration. Fractional parts of a Cc. may be measured by means of a 1 Cc. pipette graduated in one-tenth or one-twentieth divisions.

USE OF EMPIRICAL SOLUTIONS.—All standard volumetric solutions deteriorate in time, some very slowly, others rapidly, especially when not properly preserved. To restore the titer of such solutions (that is, to make them exactly normal, tenth-, or hundredth-normal, as the case may be) each time they are to be used, involves an unnecessary waste of time. If one accurately standardized solution be always available, it is not necessary that the other volumetric solutions employed in conjunction with it be diluted to exactly correspond, Cc. for Cc., so long as the exact ratio is known.

The percentage strength of any empirical solution as compared with a standard volumetric solution is ascertained by experiment, then the number of Cc. of the empirical solution consumed in the titration of the substance is multiplied by its percentage strength, which result represents the equivalent volume of the true standard solution.

Example.—One gramme of a sample of potassium carbonate required for neutralization 22 Cc. of an empirical solution of hydrochloric acid. In a trial experiment, 16 Cc. of this weak solution were required to neutralize 10 Cc. of a standard normal potassium hydroxide V.S. The former is therefore of 62.5 per cent. strength (for $16 : 10 :: 100 : x$. $x = 62.5$), hence the 22 Cc. of empirical solution consumed represent 13.75 Cc. (62.5 per cent. of 22) of standard normal hydrochloric acid V.S. Then if 1 Cc. of $\frac{N}{1}$ hydrochloric acid V.S. = 0.068635 Gm. of potassium carbonate, 13.75 Cc. would be equivalent to 13.75×0.068635 , or 0.9436+ Gm. of carbonate.

133. Alkaline Cupric Tartrate Volumetric Solution.

[FEHLING'S SOLUTION.]

A. The Copper Solution.—Dissolve 34.67 (34.6663) Gm. of carefully selected, small crystals of pure cupric sulphate [*Cupri Sulphas*, U. S. P.], showing no trace of efflorescence or of adhering moisture, in a sufficient quantity of water to make the solution measure, at 25° C. (77° F.), exactly 500 Cc.

Keep this solution in small, well-stoppered bottles.

B. The Alkaline Tartrate Solution.—Dissolve 173 Gm. of crystallized potassium and sodium tartrate [*Potassii et Sodii Tartras*, U. S. P.], and 75 Gm. of potassium hydroxide [*Potassii Hydroxidum*, U. S. P.], in a sufficient quantity of water to make the solution measure, at 25° C. (77° F.), exactly 500 Cc.

Keep the solution in small, rubber-stoppered bottles.

For use, mix exactly equal volumes of the two solutions at the time required.

One Cubic Centimeter of the mixed solution is the equivalent of:

	Gramme.
Cupric Sulphate, crystallized, $\text{CuSO}_4 + 5\text{H}_2\text{O}$	0.03467
Cupric Tartrate, $\text{Cu}_2\text{C}_4\text{H}_4\text{O}_6 + 3\text{H}_2\text{O}$	0.03688
Cane Sugar (Inverted).....	0.00475
Glucose, anhydrous, $\text{C}_6\text{H}_{12}\text{O}_6$	0.00500
Milk Sugar, anhydrous, $\text{C}_{12}\text{H}_{22}\text{O}_{11}$	0.00678

134. Tenth-Normal Bromine Volumetric Solution.

[KOPPESCHAAR'S SOLUTION.]

Br = 79.36.

7.936 Gm. in 1000 Cc.

Dissolve 3.2 Gm. of potassium bromate (No. 81) and 50 Gm. of potassium bromide in sufficient water to measure, at or near 25° C. (77° F.), 900 Cc. Transfer 20 Cc. of this solution, by means of a pipette, into a bottle having a capacity of about 250 Cc., and provided with a glass stopper; add 75 Cc. of water and 5 Cc. of pure hydrochloric acid, and immediately insert the stopper. Shake the bottle a few times,

then remove the stopper just sufficiently to quickly introduce 5 Cc. of potassium iodide T.S., taking care that no bromine vapors escape, and immediately stopper the bottle. Agitate the bottle thoroughly, remove the stopper and rinse it and the neck of the bottle with a little water so that the washings flow into the bottle, and then add from a burette tenth-normal sodium thiosulphate V.S. until the brown iodine tint is just discharged. Note the number of Cc. of the sodium thiosulphate V.S. thus consumed, and then dilute the bromine solution so that equal volumes of it and of tenth-normal sodium thiosulphate V.S. will exactly correspond to each other under the conditions mentioned above.

EXAMPLE.—Assuming that the 20 Cc. of the bromine solution have required 25.2 Cc. of the sodium thiosulphate V.S. to completely discharge the iodine tint, then each 20 Cc. of the bromine solution must be diluted to 25.2 Cc. Thus, if 850 Cc. of the solution remain, it must be diluted with water to measure 1071 Cc.

After the solution is thus diluted, a new trial should be made in the manner above described, in which 25 Cc. of the tenth-normal sodium thiosulphate V.S. should just discharge the tint of the iodine liberated by the bromine set free from 25 Cc. of the standard bromine solution.

Keep the solution in dark amber-colored, glass-stoppered bottles.

One Cubic Centimeter of Tenth-Normal Bromine V.S. is the equivalent of :

Bromine, Br.....	Gramme.
Phenol, C_6H_5OH	0.007936
	0.001556

135. Normal Hydrochloric Acid Volumetric Solution.

HCl = 36.18. 36.18 Gm. in 1000 Cc.

Mix 130 Cc. of hydrochloric acid of specific gravity 1.158 with sufficient water to measure 1000 Cc.

Of this liquid (which is still too concentrated) carefully measure, from a burette, 10 Cc. into a flask or porcelain dish, and after diluting with about double its volume of water, add 2 drops of methyl-orange T.S., then gradually add, from a burette, a freshly standardized normal potassium hydroxide V.S., until the red tint of the solution changes, after vigorous shaking, to a permanent pale yellow. Note the number of Cc. of potassium hydroxide V.S. consumed, and then dilute the acid solution so that equal volumes of this and of the normal potassium hydroxide V.S. neutralize each other at 25° C. (77° F.).

EXAMPLE.—Assuming that 10 Cc. of the acid solution first prepared required exactly 11 Cc. of normal potassium hydroxide V.S., each 10 Cc. of the former must be diluted to 11 Cc., or the whole of the remaining acid solution in the same proportion at 25° C. (77° F.). Thus, if 950 Cc. should remain, 95 Cc. of water must be added.

After the liquid is thus diluted, a new trial should be made in the manner above described, in which 50 Cc. of the acid solution should require for neutralization exactly 50 Cc. of normal potassium hydroxide V.S. If necessary, a new adjustment should then be made to render the correspondence perfect at 25° C. (77° F.).

One Cubic Centimeter of Normal Hydrochloric Acid V.S. is the equivalent of :

Hydrochloric Acid, absolute, HCl.....	Gramme.
	0.03618

NOTE.—Normal hydrochloric acid is in every respect equivalent in neutralizing power to normal sulphuric acid (see No. 152), and may be employed, except in special cases, for the same purposes. However, preference is generally given to the normal sulphuric acid V.S.

136. Half-Normal Hydrochloric Acid Volumetric Solution.

HCl = 36.18. 18.09 Gm. in 1000 Cc.

Dilute 500 Cc. of normal hydrochloric acid V.S. with sufficient distilled water to measure exactly 1000 Cc. at 25° C. (77° F.).

One Cubic Centimeter of Half-Normal Hydrochloric Acid V.S. is the equivalent of :

137. Tenth-Normal Iodine Volumetric Solution.

I = 125.9. 12.59 Gm. in 1000 Cc.

Tenth-normal iodine V.S. may be prepared according to either of the following methods:

I. Dissolve 12.59 Gm. of pure iodine (see below) in a solution of 18 Gm. of potassium iodide in 300 Cc. of water. Then add sufficient water to make the solution measure, at 25° C. (77° F.), exactly 1000 Cc. Unless freshly prepared, its strength should always be determined anew at the time it is used. Transfer the solution to glass-stoppered vials.

Preparation of Pure Iodine.—Heat powdered iodine [*Iodum*, U. S. P.] in a porcelain dish placed over a bath of boiling water for twenty minutes, and stir it constantly with a glass rod, so that adhering moisture, cyanogen iodide, and most of the iodine bromide and iodine chloride, if present, may be vaporized. Then transfer the iodine to a porcelain or other non-metallic mortar, and triturate it with about 5 per cent. of its weight of dry potassium iodide, so as to decompose any remaining iodine bromide and iodine chloride. Then return the mass to the dish, cover it with a glass funnel, and heat the dish carefully on a sand-bath. Detach the sublimed, pure iodine, and, after pulverizing and drying for twenty-four hours over calcium chloride, keep it in well-stoppered bottles, in a cool place.

II. Tenth-normal iodine V.S. may also be prepared as follows:

Dissolve about 14 Gm. of iodine [*Iodum*, U. S. P.] in a solution of 18 Gm. of potassium iodide [*Potassii Iodidum*, U. S. P.] in about 300 Cc. of water, diluting finally to 1000 Cc. Of this solution (which is too concentrated), carefully measure from a burette 10 Cc. into a flask, then add gradually and cautiously, from a burette, tenth-normal sodium thiosulphate V.S. (shaking constantly) until the color of the solution is discharged. Note the number of Cc. of the sodium thiosulphate V.S. consumed, and then dilute the iodine solution so that any known volume of the latter will require for decolorization exactly the same volume of the tenth-normal sodium thiosulphate V.S.

EXAMPLE.—Assuming that 10 Cc. of the iodine solution required 10.8 Cc. of the tenth-normal sodium thiosulphate V.S. for decolorization, then each 10 Cc. of the former must be diluted to 10.8 Cc., or each 100 Cc. of the iodine solution to 108 Cc. at 25° C. (77° F.). After the solution is thus diluted, a new trial should be made in the manner above described, in which 50 Cc. of the tenth-normal iodine V.S. should require exactly 50 Cc. of the tenth-normal sodium thiosulphate V.S. for complete decolorization. If necessary, a new adjustment should be made to render the correspondence perfect.

One Cubic Centimeter of Tenth-Normal Iodine V.S. is the equivalent of:

	Gramme.
Iodine, I	0.01259
Arsenic, As	0.00372
Arsenic Trioxide (Arsenous acid), As ₂ O ₃	0.004911
Iron, Fe	0.002775
Potassium Sulphite, crystallized, K ₂ SO ₃ + 2H ₂ O	0.009648
Sodium Bisulphite, NaHSO ₃	0.005168
Sodium Thiosulphate (Hyposulphite), crystals, Na ₂ S ₂ O ₃ + 5H ₂ O	0.024646
Sodium Sulphite, crystallized, Na ₂ SO ₃ + 7H ₂ O	0.012520
Sulphur Dioxide, SO ₂	0.003180
Antimony and Potassium Tartrate, crystallized, 2K(SbO)C ₄ H ₄ O ₆ + H ₂ O	0.016495

138. Tenth-Normal Oxalic Acid Volumetric Solution.H₂C₂O₄ + 2H₂O = 125.10. 6.255 Gm. in 1000 Cc.

Dissolve 6.4 Gm. of pure oxalic acid (see No. 73) in sufficient water to measure 1000 Cc.

Into a flask, accurately measure, from a burette, 10 Cc. of a *freshly standardized* tenth-normal potassium hydroxide V.S., dilute with about 20 Cc. of water, add 3 to 5 drops of phenolphthalein T.S. and heat to boiling. From a burette gradually add the oxalic acid solution (which is still too concentrated) until the red tint of the alkali solution fails to reappear after vigorous shaking and boiling. Note the number of Cc. of the oxalic acid solution consumed, and then dilute it so that equal volumes of this and of the tenth-normal potassium hydroxide V.S. neutralize each other at 25° C. (77° F.). It deteriorates on standing.

EXAMPLE.—Assuming that the 10 Cc. of the tenth-normal potassium hydroxide V.S. required exactly 9.5 Cc. of the oxalic acid solution, then each 9.5 Cc. of the latter must be diluted to 10 Cc., or the whole of the remaining acid solution in the same proportion at 25° C. (77° F.). Thus, if 950 Cc. of the oxalic acid solution should remain, 50 Cc. of water must be added.

After the liquid is thus diluted, a new trial should be made in the manner above described, in which 50 Cc. of tenth-normal potassium hydroxide V.S. should require for neutralization exactly 50 Cc. of the oxalic acid solution at 25° C. (77° F.). If necessary, a new adjustment should then be made to render the correspondence perfect.

NOTE.—Tenth-normal oxalic acid V.S. is in every respect equivalent in neutralizing power to any other tenth-normal acid V.S. with either litmus or phenolphthalein T.S. as indicator. Its most important use is in standardizing tenth-normal potassium permanganate V.S.

One Cubic Centimeter of Tenth-Normal Oxalic Acid V.S. is the equivalent of:

	Gramme.
Oxalic Acid, crystallized, H ₂ C ₂ O ₄ + 2H ₂ O	0.006255
Ammonia Gas, NH ₃	0.001693
Calcium Hydroxide, Ca(OH) ₂	0.003678
Lead Subacetate, Pb ₂ O(C ₂ H ₃ O ₂) ₂	0.0135935
Manganese Dioxide, precipitated, MnO ₂	0.004318
Potassium Hydroxide, KOH	0.005574
Potassium Permanganate, KMnO ₄	0.0031396
Sodium Hydroxide, NaOH	0.003976

139. Tenth-Normal Potassium Dichromate Volumetric Solution. $K_2Cr_2O_7 = 292.28.$

4.8713 Gm. in 1000 Cc.

Dissolve 4.8713 Gm. of pure potassium dichromate, which has been pulverized and dried at 120° C. (248° F.) (see Reagent No. 85), in sufficient water to measure, at 25° C. (77° F.), exactly 1000 Cc.

When used with phenolphthalein as indicator, to neutralize alkalies, the volumetric solution of potassium dichromate is tenth-normal when it contains 14.614 Gm. in 1000 Cc. It is then the exact equivalent of any tenth-normal acid V.S., each Cc. being equivalent to the amounts of alkalies quoted under such acids.

When used as an oxidizing agent to convert ferrous into ferric salts, or to liberate iodine from potassium iodide, the solution just mentioned (containing 14.614 Gm. in 1000 Cc.) has the effect of a $\frac{3N}{10}$ volumetric solution, and a solution of one-third of this strength, containing 4.8713 Gm. in 1000 Cc., has the value of a tenth-normal solution, and is the equivalent of an equal volume of tenth-normal potassium permanganate V.S., or, in the case of iodine liberated from potassium iodide, it is the equivalent of an equal volume of tenth-normal sodium thiosulphate V.S. For titrating iron in ferrous compounds, it is used in the following manner. Introduce the aqueous solution of the ferrous salt into a flask, and, if it is not already acid, render it so with sulphuric acid. Now add, gradually, tenth-normal potassium dichromate V.S. from a burette, with agitation, until a drop taken out upon a white surface no longer becomes blue when mixed with a drop of freshly prepared potassium ferricyanide T.S.

Tenth-normal potassium dichromate V.S. may also be used, in conjunction with potassium iodide (from which it liberates iodine) and sulphuric acid, for adjusting the titer of sodium thiosulphate V.S. and thus that of the iodine V.S.

One Cubic Centimeter of Tenth-Normal Potassium Dichromate V.S. is the equivalent of:

	Gramme.
Potassium Dichromate, $K_2Cr_2O_7$	0.0048713
Iron, Fe, in ferrous compounds	0.00555
Ferrous Carbonate, $FeCO_3$	0.011505
Ferrous Sulphate, anhydrous, $FeSO_4$	0.015085
Ferrous Sulphate, crystallized, $FeSO_4 + 7H_2O$	0.027601
Ferrous Sulphate, dried, $2FeSO_4 + 3H_2O$	0.017767
Sodium Thiosulphate, $Na_2S_2O_3 + 5H_2O$	0.024646

140. Normal Potassium Hydroxide Volumetric Solution.

KOH = 55.74.

55.74 Gm. in 1000 Cc.

Dissolve 75 Gm. of potassium hydroxide [*Potassii Hydroxidum*, U. S. P.], in sufficient water to measure about 1050 Cc., and fill a burette with a portion of this liquid.

Into a flask of the capacity of about 300 Cc., introduce 9.339 Gm. of potassium bitartrate, which has been purified and dried as directed under No. 80, and 160 Cc. of distilled water. Boil the liquid until solution has taken place, add from 3 to 5 drops of phenolphthalein T.S., followed by the cautious addition, from a burette, of the potassium hydroxide solution, frequently agitating the flask, boiling, and, toward the end of the operation, reducing the flow to drops until the red color produced by its influx no longer disappears on shaking, but is not deeper than pale pink. Note the number of Cc. of the potassium hydroxide solution consumed, and then dilute the remainder of the solution so that exactly 50 Cc. of the diluted liquid at 25° C. (77° F.) shall be required to neutralize the 9.339 Gm. of potassium bitartrate used.

EXAMPLE.—Assuming that 40 Cc. of the stronger solution of potassium hydroxide first prepared had been consumed in the trial, then each 40 Cc. must be diluted to 50 Cc., or the whole of the remaining solution in the same proportion at 25° C. (77° F.). Thus, if 1000 Cc. should be still remaining, this must be diluted with water to 1250 Cc.

After the liquid is thus diluted, a new trial should be made in the manner above described, in which 50 Cc. of the diluted solution should exactly neutralize 9.339 Gm. of potassium bitartrate at 25° C. (77° F.). If necessary, a new adjustment should then be made to render the correspondence perfect.

NOTE.—Solutions of caustic alkalies absorb carbon dioxide from the atmosphere, and thereby change their titer when used with litmus T.S., or phenolphthalein T.S., as indicator (methyl-orange T.S. is not affected by the presence of carbonic acid). Hence the volumetric solutions should be preserved in bottles provided with well-fitting rubber stoppers, or, better still, these should be provided with tubes filled with soda-lime (a mixture of caustic soda and lime); the tubes pass through a perforation in the rubber stoppers, and thus absorb the carbon dioxide and prevent its access to the solution. If the solution is kept in a burette for any length of time, the same provision with a soda-lime tube should be observed.

In place of potassium hydroxide V.S., sodium hydroxide V.S. (see No. 150) may be used, in the same manner and in the same quantity. Potassium hydroxide V.S., however, is preferable, since it foams less, and attacks glass more slowly.

One Cubic Centimeter of Normal Potassium Hydroxide V.S. is the equivalent of:

Tartaric Acid, crystallized, $\text{H}_2\text{C}_4\text{H}_4\text{O}_6$	0.07446
Trichloroacetic Acid, CCl_3COOH	0.16212

141. Tenth-Normal Potassium Hydroxide Volumetric Solution.

$\text{KOH} = 55.74$. 5.574 Gm. in 1000 Cc.

Dilute 100 Cc. of freshly standardized normal potassium hydroxide V.S. with sufficient distilled water to measure, at 25°C . (77°F .), exactly 1000 Cc.

This solution may also be prepared and standardized directly with potassium bitartrate, as directed under normal potassium hydroxide V.S., employing for this purpose 0.9339 Gm. of the former and a solution of about 7.5 Gm. of potassium hydroxide [*Potassii Hydroxidum*, U. S. P.] in 1000 Cc. of distilled water. Fifty Cc. of the prepared tenth-normal solution at 25°C . (77°F .) should exactly neutralize 0.9339 Gm. of potassium bitartrate (No. 80).

NOTE.—The same precautions should be taken for protecting this solution from carbon dioxide of the air as are directed under normal potassium hydroxide V.S.

One Cubic Centimeter of Tenth-Normal Potassium Hydroxide V.S. is the equivalent of:

	Gramme.
Potassium Hydroxide, KOH	0.005574
Sulphuric Acid, absolute, H_2SO_4	0.0048675

142. Fiftieth-Normal Potassium Hydroxide Volumetric Solution.

$\text{KOH} = 55.74$. 1.1148 Gm. in 1000 Cc.

Dilute 20 Cc. of a freshly standardized normal or 200 Cc. of tenth-normal potassium hydroxide V.S. with sufficient distilled water to measure, at 25°C . (77°F .), exactly 1000 Cc. This standard solution is employed in conjunction with the tenth-normal sulphuric acid V.S. in the titration of alkaloids, with hematoxylin, cochineal, or iodeosin T.S. as indicators.

NOTE.—The same precautions should be taken for protecting this solution from carbon dioxide of the air as are directed under normal potassium hydroxide V.S. It should be renewed at frequent intervals.

One Cubic Centimeter of Fiftieth-Normal Potassium Hydroxide V.S. is the equivalent of:

143. Hundredth-Normal Potassium Hydroxide Volumetric Solution.

$\text{KOH} = 55.74$. 0.5574 Gm. in 1000 Cc.

Dilute 10 Cc. of normal or 100 Cc. of tenth-normal potassium hydroxide V.S. with sufficient water to measure, at 25°C . (77°F .), exactly 1000 Cc. The solution must be frequently renewed.

One Cubic Centimeter of Hundredth-Normal Potassium Hydroxide V.S. is the equivalent of:

	Gramme.
Potassium Hydroxide, KOH	0.0005574
Sulphuric Acid, absolute, H_2SO_4	0.00048675

144. Half-Normal Alcoholic Potassium Hydroxide Volumetric Solution.

$\text{KOH} = 55.74$. 27.87 Gm. in 1000 Cc.

Dissolve about 40 Gm. of potassium hydroxide [*Potassii Hydroxidum*, U. S. P.], which has been broken into small pieces, in about 20 Cc. of water, and add sufficient alcohol [*Alcohol*, U. S. P.], to measure 1000 Cc. After setting aside in a well-stoppered bottle for one day, the clear supernatant solution should be quickly decanted into a bottle provided with a well-fitted rubber stopper.

Into a flask of the capacity of about 300 Cc., introduce 1.8678 Gm. of potassium bitartrate, which has been purified and dried, as directed under No. 80, and about 100 Cc. of distilled water. Heat the solution to the boiling point, add 5 drops of phenolphthalein T.S., followed by the cautious addition, from a burette, of the potassium hydroxide solution, frequently agitating the flask, boiling, and, toward the end of the operation, reducing the flow to drops until the red color produced by its influx no longer disappears on shaking, but is not deeper than pale pink. Note the number of Cc. of the alcoholic potassium hydroxide solution consumed, and then dilute the remainder of the solution with alcohol so that exactly 20 Cc. of the diluted liquid shall be required to neutralize the 1.8678 Gm. of potassium bitartrate used.

EXAMPLE.—Assuming that 12.5 Cc. of the stronger alcoholic solution of potassium hydroxide first prepared had been consumed in the trial, then each 12.5 Cc. must be diluted with alcohol to 20 Cc., or the whole of the remaining solution in the same proportion at 25° C. (77° F.). Thus, if 980 Cc. should remain, this must be diluted with alcohol to measure 1568 Cc.

Half-Normal Alcoholic Potassium Hydroxide V.S. may also be prepared as follows: Of the above described concentrated alcoholic potassium hydroxide solution, carefully measure, from a burette, 20 Cc. into a flask, and, after diluting with about 50 Cc. of water, add about 5 drops of phenolphthalein T.S., heat to a boiling temperature, and add, from a burette, half-normal hydrochloric acid V.S., frequently agitating the flask, and, toward the end of the operation, reducing the flow to drops until the red color is just discharged. Note the number of Cc. of the half-normal hydrochloric acid V.S. consumed, and then dilute the remainder of the solution with alcohol so that equal volumes of this and of the half-normal hydrochloric acid V.S. neutralize each other at 25° C. (77° F.).

Should half-normal hydrochloric acid V.S. not be available, standardization can be carried out in the same manner with normal hydrochloric acid V.S., two volumes of the alcoholic potassium hydroxide being made to correspond with one volume of the standard acid.

NOTE.—This solution should be kept in bottles provided with a well-fitted rubber stopper and protected from the light. Owing to the readiness with which this standard solution loses its titer, blank tests should be performed whenever it is employed in titrations.

One Cubic Centimeter of Half-Normal Alcoholic Potassium Hydroxide V.S. is the equivalent of:

Potassium Hydroxide, KOH	Gramme.
Borneol, $C_{10}H_{18}O$	0.02787

Santalol, $C_{15}H_{26}O$	0.09834
	0.11026

145. Tenth-Normal Potassium Permanganate Volumetric Solution.

$2KMnO_4 = 313.96$.

3.1396 Gm.¹ in 1000 Cc.

Introduce about 3.3 Gm. of pure, crystallized potassium permanganate [*Potassii Permanganas*, U. S. P.] into a flask, add 1000 Cc. of distilled water, and boil for about five minutes. Close the flask with a plug of purified cotton, and set aside for at least two days, so that suspended matter may deposit. After the lapse of this time, pour off the clear portion of the solution into a glass-stoppered bottle.

The water to be employed for diluting this solution (which is still too concentrated) should be prepared as directed under Distilled Water [*Aqua Destillata*, U. S. P.], adding, however, about 1 Gm. of potassium permanganate to the water in the retort before beginning the distillation.

I. Introduce into a flask 10 Cc. of an accurately standardized tenth-normal oxalic acid V.S., add 1 Cc. of pure, concentrated sulphuric acid, and before this mixture cools, gradually add, from a burette provided with a glass stop-cock, small quantities of the permanganate solution to be standardized, shaking the flask after each addition and reducing the flow to drops toward the end of the operation. When the last drop of the permanganate solution added is no longer decolorized, but imparts a pinkish tint to the liquid, which remains permanent for one-half minute, note the number of Cc. consumed, and then dilute the trial permanganate solution with the specially prepared distilled water so that it will correspond, volume for volume, at 25° C. (77° F.), with the tenth-normal oxalic acid V.S. (note example under II.).

II. Tenth-normal potassium permanganate V.S. may also be standardized as follows:

To a solution of about 1 Gm. of potassium iodide [*Potassii Iodidum*, U. S. P.], in 10 Cc. of diluted sulphuric acid, contained in a flask, add, from a burette provided with a glass stop-cock, 20 Cc. of the potassium permanganate solution to be standardized; then dilute the mixture at once with about 200 Cc. of distilled water. An accurately standardized tenth-normal sodium thiosulphate V.S. is then slowly added from a burette, while the mixture is vigorously shaken, until the color is discharged. Note the number of Cc. of the latter consumed, then dilute the permanganate solution so that equal volumes of the two solutions correspond to each other under the same conditions at 25° C. (77° F.).

EXAMPLE.—Assuming that 25 Cc. of the tenth-normal sodium thiosulphate V.S. were required to decolorize the liberated iodine of the mixture, then each 20 Cc. of the potassium permanganate solution must be diluted with the specially prepared distilled water to 25 Cc., or the whole of the remaining solution in the same proportion. Thus, if 920 Cc. remain, it should be diluted to measure 1150 Cc. at 25° C. (77° F.).

After the potassium permanganate solution is thus diluted, a new trial should be made in the manner above described, in which 20 Cc. of this solution should require exactly 20 Cc. of the tenth-normal sodium thiosulphate V.S. to decolorize the mixture. If necessary, a new adjustment should be made to render the correspondence perfect.

NOTE.—When potassium permanganate V.S. is to be prepared for immediate use, this may be done as follows: Dissolve about 3.3 Gm. of pure, crystallized potassium permanganate in 1000 Cc. of recently

¹ The exact quantity is never weighed, but the solution is adjusted directly by oxalic acid or indirectly with sodium thiosulphate.

boiled and cooled pure water. This is then standardized by either of the above methods and diluted accordingly with recently boiled and cooled pure water. Potassium permanganate V.S. made by this method without the preliminary boiling and standing deteriorates readily, hence should be verified each time it is used.

Potassium permanganate V.S. should be kept in well-closed glass-stoppered bottles, and only burettes provided with glass stop-cocks should be employed in titrating with it. Even when properly prepared and preserved, this solution should be restandardized frequently.

One Cubic Centimeter of Tenth-Normal Potassium Permanganate V.S. is the equivalent of:

146. Tenth-Normal Potassium Sulphocyanate Volumetric Solution.

[VOLHARD'S SOLUTION.]

$\text{KSCN} = 96.53$. 9.653 Gm. in 1000 Cc.

Dissolve 10 Gm. of crystals of pure potassium sulphocyanate (No. 96) in 1000 Cc. of water.

This solution is too concentrated, and has to be adjusted so as to correspond in strength exactly with tenth-normal silver nitrate V.S. For this purpose, introduce into a flask 10 Cc. of tenth-normal silver nitrate V.S., 3 Cc. of ferric ammonium sulphate T.S., and 3 Cc. of nitric acid (free from nitrous compounds), and dilute the liquid with about 100 Cc. of distilled water. To this mixture add, from a burette, in small portions at a time, the sulphocyanate solution. At first, a white precipitate of silver sulphocyanate appears, then, every drop falling from the burette is surrounded by a deep brownish-red color produced by ferric sulphocyanate, which disappears on vigorous shaking of the flask as long as any of the silver nitrate remains unchanged. When all the silver has been converted into sulphocyanate, a single additional drop of the potassium sulphocyanate solution produces a brownish-red color which no longer disappears on shaking, but communicates a perceptible pale reddish-brown tint to the contents of the flask. Note the number of Cc. of the potassium sulphocyanate solution used, and dilute the whole of the remaining solution so that equal volumes of this and of the tenth-normal silver nitrate V.S., at 25°C . (77°F .), will be required to produce the permanent reddish-brown tint. (The same depth of pale reddish brown tint to which the volumetric solution is adjusted must be attained when the solution is used for volumetric assays.)

After the dilution, a new trial should be made, in which 50 Cc. of tenth-normal silver nitrate V.S., 5 Cc. of ferric ammonium sulphate T.S., 5 Cc. of nitric acid, and 200 Cc. of water are used, and there should be required exactly 50 Cc. of the potassium sulphocyanate solution, at 25°C . (77°F .), to produce the same depth of a permanent pale reddish-brown tint.

If necessary, a new adjustment should be made, to render the correspondence perfect.

One Cubic Centimeter of Tenth-Normal Potassium Sulphocyanate V.S. is the equivalent of:

	Gramme.
Potassium Sulphocyanate, KSCN	0.009653
Silver, Ag	0.010712
Silver Nitrate, AgNO_3	0.016869

147. Tenth-Normal Silver Nitrate Volumetric Solution.

$\text{AgNO}_3 = 168.69$. 16.869 Gm. in 1000 Cc.

Dissolve 16.869 Gm. of silver nitrate [*Argenti Nitras*, U. S. P.] which, previous to weighing, has been pulverized and dried in a covered porcelain crucible in an air-bath at 130°C . (266°F .) for one hour, in sufficient water to measure, at 25°C . (77°F .), exactly 1000 Cc.

Keep the solution in dark amber-colored, glass-stoppered vials, carefully protected from dust and sunlight.

NOTE.—Titration by tenth-normal silver nitrate V.S. may be conducted in various ways, adapted to the special preparation to be tested:

a. *The titration of soluble chlorides and bromides.*—To the solution of an accurately weighed quantity of the salt, contained in either a porcelain dish or a flask placed on a white surface, sufficient potassium chromate T.S. is added to impart a yellow tint, then the tenth-normal silver nitrate V.S. is slowly added from a burette, stirring or agitating constantly until the mixture acquires a permanent red tint, due to the formation of red silver chromate. This method is only suitable for neutral solutions.

b. *The titration of free hydrobromic, hydrochloric, and hydriodic acids or their salts in acid solution, known as the Volhard or Thiocyanate (Sulphocyanate) method of residual titration.*—An accurately measured excess of tenth-normal silver nitrate V.S. is added to the solution of the halogen acid or its salt, and then acidified with pure nitric acid, and the indicator (ferric ammonium sulphate T.S.) added; then the uncombined excess of the silver nitrate V.S. is determined by titrating back with tenth-normal potassium sulphocyanate V.S., the end-reaction being the formation of a permanent pale reddish-brown tint (due to

ferric sulphocyanate). The volume of the silver nitrate V.S. originally added, less that of the potassium sulphocyanate V.S. consumed, will give the number of Cc. of the former which were required for the precipitation of the halogen. The quantity of nitric acid added should be sufficient to remove the yellow color produced by the addition of the indicator.

c. *Titration till the first appearance of a permanent precipitate.*—This method is applicable in the estimation of the alkali cyanides and hydrocyanic acid. When the solution is used by this method it is fifth-normal instead of tenth-normal solution.

One Cubic Centimeter of Tenth-Normal Silver Nitrate V.S. is the equivalent of:

148. Tenth-Normal Sodium Chloride Volumetric Solution.

$\text{NaCl} = 58.06$.

5.806 Gm. in 1000 Cc.

Dissolve 5.806 Gm. of pure sodium chloride (see below) in sufficient water to measure, at 25°C . (77°F), exactly 1000 Cc.

Pure Sodium Chloride may be prepared by passing a current of dry hydrochloric acid gas into a saturated aqueous solution of the purest commercial sodium chloride, collecting the crystalline precipitate on a filter, washing with a little pure concentrated hydrochloric acid, draining, pulverizing, and igniting it gently in a crucible heated to low redness, to expel all traces of free acid. Care should be taken to avoid fusion.

One Cubic Centimeter of Tenth-Normal Sodium Chloride V.S. is the equivalent of:

	Gramme.
Sodium Chloride, NaCl	0.005806
Silver, Ag	0.010712
Silver Nitrate, AgNO_3	0.016869
Silver Oxide, Ag_2O	0.011506

149. Double-Normal Sodium Hydroxide Volumetric Solution.

$\text{NaOH} = 39.76$.

79.52 Gm. in 1000 Cc.

Dissolve 90 Gm. of sodium hydroxide [*Sodii Hydroxidum*, U. S. P.] in sufficient water to measure about 1000 Cc.

For the standardization of this approximate solution of sodium hydroxide proceed as directed under normal potassium hydroxide V.S. (see No. 140); 25 Cc. of the volumetric solution, at 25°C . (77°F), should exactly neutralize 9.339 Gm. of pure potassium bitartrate (see No. 80).

NOTE.—The same precautions should be taken for protecting this solution from the carbon dioxide of the air as are prescribed for normal potassium hydroxide V.S. (see No. 140).

150. Normal Sodium Hydroxide Volumetric Solution.

$\text{NaOH} = 39.76$.

39.76 Gm. in 1000 Cc.

Dissolve 54 Gm. of sodium hydroxide [*Sodii Hydroxidum*, U. S. P.] in sufficient water to measure about 1050 Cc., and fill a burette with a portion of this liquid.

For the standardization of this approximate solution of sodium hydroxide, proceed as directed under normal potassium hydroxide V.S. (see No. 140); 50 Cc. of the volumetric solution, at 25°C . (77°F), must exactly neutralize 9.339 Gm. of pure potassium bitartrate.

NOTE.—The same precautions should be taken for protecting this solution from the carbon dioxide of the air as are prescribed for normal potassium hydroxide V.S. (see No. 140).

This solution may be employed in place of the normal potassium hydroxide V.S. (see No. 140), volume for volume.

One Cubic Centimeter of Normal Sodium Hydroxide V.S. is the equivalent of:

	Gramme.
Sodium Hydroxide, NaOH	0.03976
Boric Acid, H ₃ BO ₃	0.06154
Formaldehyde, CH ₂ O	0.02979
Trichloroacetic Acid, HC ₂ Cl ₃ O ₂	0.16212

151. Tenth-Normal Sodium Thiosulphate Volumetric Solution.

Dissolve 30 Gm. of sodium thiosulphate (see No. 113) in sufficient distilled water to measure 1000 Cc. This trial solution, which is too concentrated, is standardized as follows:

To a solution of about 1 Gm. of potassium iodide [*Potassii Iodidum*, U. S. P.] in 10 Cc. of diluted sulphuric acid contained in a flask of about 500 Cc. capacity, add slowly, from a burette, 20 Cc. of tenth-normal potassium dichromate V.S., shaking after each addition. Place a watch-glass on the mouth of the flask and allow it to stand for five minutes, then dilute the solution with about 250 Cc. of distilled water, add some starch T.S., and then, from a burette, the trial solution of sodium thiosulphate, in small portions at a time, shaking after each addition, and, toward the end of the operation, reducing the flow to drops, until the blue color of the mixture changes to a light green; note the number of Cc. of the trial sodium thiosulphate solution consumed. Then dilute the sodium thiosulphate solution so that equal volumes of it and the tenth-normal potassium dichromate V.S. will exactly correspond to each other under the above conditions, at 25° C. (77° F.).

EXAMPLE.—Assuming that 16 Cc. of the trial sodium thiosulphate solution were required to decolorize the liberated iodine of the mixture, then each 16 Cc. of this solution must be diluted to 20 Cc. so that it will correspond in volume to the tenth-normal potassium dichromate V.S. added, or the whole of the remaining solution in the same proportion at 25° C. (77° F.). Thus, if 984 Cc. of the sodium thiosulphate solution are remaining, this should be diluted to measure 1230 Cc. After the sodium thiosulphate solution is thus diluted, a new trial should be made in the manner above described, in which exactly 20 Cc. of this solution should be required to decolorize the iodine liberated by 20 Cc. of the tenth-normal dichromate V.S. If necessary, a new adjustment should be made to render the correspondence perfect.

Keep the solution in glass-stoppered bottles, carefully protected from dust.

NOTE.—When this solution is to be used, fill a burette with it, place the liquid to be tested either for the free iodine it already contains, or for that which it liberates from an excess of potassium iodide added to it, in a flask, and gradually add small portions of the solution from the burette, shaking after each addition, and, toward the end of the operation, reducing the flow to drops, until the color is discharged.

One Cubic Centimeter of Tenth-Normal Sodium Thiosulphate V.S. is the equivalent of:

	Gramme.
Sodium Thiosulphate (Hyposulphite), Na ₂ S ₂ O ₃ + 5H ₂ O	0.024646
Bromine, Br	0.007936
Chlorine, Cl	0.003518
Chromium Trioxide, CrO ₃	0.003311
Iodine, I	0.01259
Iron, Fe, in ferric salts	0.00555
Potassium Bromate, KBrO ₃	0.002764

152. Normal Sulphuric Acid Volumetric Solution.

Carefully mix 30 Cc. of pure, concentrated sulphuric acid, of specific gravity 1.826 at 25° C. (77° F.), with sufficient water to measure about 1050 Cc., and allow the liquid to cool to 25° C. (77° F.). Measure from a burette 10 Cc. of this liquid (which is yet too concentrated) into a flask, add 2 drops of methyl-orange T.S., and afterwards, from a burette, a freshly standardized normal potassium hydroxide V.S., shaking after each addition, and, toward the end of the operation, reducing the flow to drops, until the red tint of the solution changes to a permanent pale yellow after thorough shaking. Note the number of Cc. of normal potassium hydroxide V.S. consumed. Then dilute the sulphuric acid solution so that equal volumes of this and of normal potassium hydroxide V.S., at 25° C. (77° F.), exactly neutralize each other.

EXAMPLE.—Assuming that 10 Cc. of the acid solution first prepared had required exactly 11.2 Cc. of normal potassium hydroxide V.S., each 10 Cc. of the former must be diluted to 11.2 Cc., or each 1000 Cc. to 1120 Cc.

After the liquid is thus diluted, a new trial should be made in the manner above described, in which 50 Cc. of the acid solution should require for neutralization exactly 50 Cc. of normal potassium hydroxide V.S., at 25° C. (77° F.). If necessary, a new adjustment should be made to render the correspondence perfect.

153. Half-Normal Sulphuric Acid Volumetric Solution.

$\text{H}_2\text{SO}_4 = 97.35$.

24.3375 Gm. in 1000 Cc.

Dilute 500 Cc. of normal sulphuric acid with sufficient water to measure 1000 Cc. at 25°C . (77°F). This standard solution is chiefly employed in the titration of the organic salts of sodium and potassium in conjunction with methyl-orange as indicator. For this purpose a special experiment should be made in which an accurately measured volume of 10 Cc. of normal potassium hydroxide V.S. should, after adding 2 drops of methyl-orange T.S., require exactly 20 Cc. of the half-normal sulphuric acid V.S. for neutralization.

If necessary, an adjustment should be made to render the correspondence perfect.

One Cubic Centimeter of Half-Normal Sulphuric Acid V.S. is the equivalent of:

154. Tenth-Normal Sulphuric Acid Volumetric Solution.

$\text{H}_2\text{SO}_4 = 97.35$.

4.8875 Gm. in 1000 Cc.

Dilute 100 Cc. of normal sulphuric acid with sufficient water to measure 1000 Cc. at 25°C . (77°F). This standard solution is employed in conjunction with the fiftieth-normal potassium hydroxide V.S. in the titration of alkaloids, with hematoxylin, cochineal, or iodeosin T.S. as an indicator. For this purpose a special experiment should be made, in which an accurately measured volume of 10 Cc. of the tenth-normal sulphuric acid, after adding 1 Cc. of hematoxylin T.S. (or a sufficient quantity of the indicator to be employed), should require 50 Cc. of the fiftieth-normal potassium hydroxide V.S. for complete neutralization, at 25°C . (77°F). If necessary, an adjustment should be made to render the correspondence perfect.

One Cubic Centimeter of Tenth-Normal Sulphuric Acid V.S. is the equivalent of:

GASOMETRIC ESTIMATIONS.

(U. S. P. 8TH REV.)

In certain cases the United States Pharmacopœia (8th Rev.) directs the strength of a product or chemical substance to be determined by the volume of gas (nitrogen dioxide) given off during a definite reaction. This volume is to be determined by the nitrometer in the following manner:

Arrange a nitrometer consisting of a measuring tube (graduated for at least 50 Cc.) connected by stout rubber tubing with an open equilibrium tube (both tubes, preferably, provided with a globular expansion near the lower end) in such a manner, by suitable clamps attached to a stand, that either tube may be readily and quickly clamped at a higher or lower level. The stop-cock of the measuring tube having been opened, and the open equilibrium tube having been raised to a higher level, pour into the latter a saturated aqueous solution of sodium chloride, until the measuring tube, including the bore of the stop-cock, is completely filled. Then close the latter and fix the equilibrium tube at a low level. Having ascertained that the stop-cock is closed air-tight, and having, if necessary, wiped out the graduated tube of the nitrometer, introduce into it the prescribed quantity of the liquid to be tested, and allow this to flow slowly into the measuring tube, being careful not to admit any air. Follow it by the prescribed quantities of the several reagents (potassium iodide T.S., and normal sulphuric acid V.S.). When the reaction, which takes place at once, moderates, remove the measuring tube from its clamp, and, being careful to hold it constantly so that the liquid contained in it stands at a higher level than that in the equilibrium tube, shake its contents, without permitting any gas to pass into the open tube. When the reaction has completely ceased, restore the tube to its fastening, and allow the apparatus and contents to acquire the ordinary temperature of the room, which is assumed to be at or about 25° C. (77° F.). Then adjust the two tubes so that the liquid columns are at exactly the same level, and read off the volume of gas in the measuring tube. Multiply this figure by the weight of the substance, which is the equivalent of 1 Cc. of nitrogen dioxide (see No. 156, page 1727). The result will be the weight of the pure substance (nitrite) contained in the amount taken for the assay.

For pharmacopœial purposes the determination will be sufficiently exact if the evolved gas be measured at or near 25° C. (77° F.).

Since temperature and barometric pressure materially affect the volume of the gas, the following correction factors must be used to obtain reasonably exact results when the temperature and pressure are not nearly normal. The barometer correction is important at any locality more than 250 meters above sea-level:

Factors for Temperature Corrections.
(Normal Temperature, 25° C.)

Temperature.	Factor.	Temperature.	Factor.	Temperature.	Factor.
15° C.	1.035	22° C.	1.010	29° C.	0.987
16° C.	1.031	23° C.	1.007	30° C.	0.983
17° C.	1.028	24° C.	1.003	31° C.	0.980
18° C.	1.024	25° C.	1.000	32° C.	0.977
19° C.	1.021	26° C.	0.997	33° C.	0.974
20° C.	1.017	27° C.	0.993	34° C.	0.971
21° C.	1.014	28° C.	0.990	35° C.	0.968

EXAMPLE.—Assuming that the volume of gas read off was 44.5 Cc. at 32° C. (89.6° F.), and it is desired to ascertain the corresponding volume at 25° C. (77° F.), barometric pressure not being taken into consideration, then the 44.5 Cc. must be reduced in the proportion of 1 to 0.977 (see temperature correction factors above), or 44.5 must be multiplied by 0.977. The result will be 43.48 (43.4765) Cc. as the equivalent volume of gas at 25° C. (77° F.).

Factors for Correction for Barometric Pressure.
(Normal Barometer, 760 Mm.)

Barometer Reading.		Factor.	Barometer Reading.		Factor.
Mm.	Inches.		Mm.	Inches.	
790	31.10	1.039	660	25.98	0.868
780	30.71	1.026	650	25.59	0.855
770	30.31	1.013	640	25.20	0.842
760	29.92	1.000	630	24.80	0.829
750	29.53	0.987	620	24.41	0.816
740	29.13	0.974	610	24.02	0.803
730	28.74	0.961	600	23.62	0.789
720	28.35	0.947	590	23.23	0.776
710	27.95	0.934	580	22.83	0.763
700	27.56	0.921	570	22.44	0.750
690	27.17	0.907	560	22.05	0.737
680	26.77	0.895	550	21.65	0.724
670	26.38	0.882			

EXAMPLE.—Assuming that the volume of gas read off was 43.48 (43.4765) Cc. at 590 Mm. barometric pressure, and it is desired to ascertain the corresponding volume at normal barometric pressure (760 Mm.), temperature not being taken into consideration, then the 43.48 Cc. must be reduced in the proportion of 1 to 0.776 (see barometric correction factors above), or 43.48 must be multiplied by 0.776. The result will be 33.74 Cc. as the equivalent volume of gas at normal barometric pressure.

156. Estimation of Nitrogen Dioxide.

NO = 29.81; 1 Liter $\begin{cases} \text{at } 0^\circ \text{ C. and 760 Mm.} = 1.3396 \text{ Gm.} \\ \text{at } 25^\circ \text{ C. and 760 Mm.} = 1.2272 \text{ Gm.} \end{cases}$

One Cubic Centimeter of Nitrogen Dioxide is the equivalent of:

	At 0° C. and 760 Mm. Gramme.	At 25° C. and 760 Mm. Gramme.
Nitrogen Dioxide, NO = 29.81	0.0013396	0.0012272
Amyl Nitrite, C ₅ H ₁₁ NO ₂ = 116.24	0.0052234	0.0047851
Ethyl Nitrite, C ₂ H ₅ NO ₂ = 74.51	0.0033482	0.0030673
Sodium Nitrite, NaNO ₂ = 68.57	0.0030813	0.0028227

ALKALOIDAL ASSAY BY IMMISCIBLE SOLVENTS.

(U. S. P. 8TH REV.)

Nearly all alkaloids are practically insoluble in water, but they are soluble in alcohol, chloroform, ether, amyl alcohol, benzene, petroleum benzin, or mixtures of several of these. The salts of these alkaloids, however, are soluble in water, but practically insoluble in the above-mentioned solvents. The process of assay by immiscible solvents, which is generally known as the "shaking out" process, is based on this property of alkaloids, and it is carried out by treating liquid extracts that have been freed from alcohol, with an immiscible solvent in the presence of an excess of alkali. This liberates the alkaloid, and, on becoming free, if not so previously, it is dissolved by the immiscible solvent. This solution is then separated, transferred to another container, and shaken with an excess of acid largely diluted with water. The acid combining with the free alkaloid forms a salt, which now leaves the immiscible solvent and is found in the aqueous solution. This process is sometimes repeated, in case the alkaloidal solution is still colored. The apparatus used in this operation of shaking out is termed a "separator," and consists of an oval or pear-shaped glass vessel, with an opening at the top supplied with a well-ground glass stopper, and an outlet tube at the bottom, provided with an accurately fitting glass stop-cock. The solvents directed to be used in the U. S. P. (8th Rev.) are alcohol, chloroform, ether, and various mixtures of these containing at least 75 parts of ether in 100 parts of solvent by volume. In the case of chloroform, the solvent will collect at the bottom of the separator, and can be drawn off, but the ethereal or ether-chloroform mixture will form the upper portion of the liquid in the separator, and the

aqueous layer must first be drawn off into a suitable vessel, and the ethereal layer then transferred to another vessel. It is not necessary or desirable to shake the mixture of immiscible solvent and water violently, for a rotation of the separator or a gentle shaking for about a minute will answer all purposes. At times, an emulsion of the water and the solvent is formed, especially if the shaking is too violent, and in order to separate this, it is advisable to proceed as follows: If the solvent is heavier than the water, add more of the former, a little water, and a slight amount of alcohol; if the solvent is lighter than the water, add sufficient saturated sodium chloride solution or crystals of sodium chloride. A safe procedure to avoid the forming of emulsions is to invert the separator several times, and then to at once begin rotating to keep the solvents well mixed. To insure a complete extraction of the alkaloid, it is desirable to treat the liquid three times with the immiscible solvent, and this is to be followed by a rinsing of the empty separator with repeated small portions of the same solvent. The separator should not be filled to more than two-thirds of its capacity at any time, and if its contents should become heated by the neutralization of acid by alkali, or *vice versa*, it should be cooled to the temperature of the room, before opening the stopper, by immersing it in running water. The final operation must always be the collection of the free alkaloid by the use of a portion of the immiscible solvent, drawing this off into a beaker, rinsing with small portions of the solvent to prevent possible loss. The beaker is then placed on a water-bath and gently heated, to remove the solvent by evaporation, leaving the alkaloids in the beaker in the dry form, and usually in the condition of a resinous or varnish-like mass. It is then either weighed as such or dissolved in volumetric acid solution, delivered in measured quantity from a burette, and the excess of the acid titrated with volumetric alkali solution with the use of an indicator. Should the final residual alkaloids still be slightly colored, it is preferable to employ iodeosin as the indicator, as the alkaloidal solution contains ether and the ethereal layer retains in solution coloring matter or impurity which may be present. If the alkaloids are not colored, hematoxylin or cochineal may safely be used.

The quantity of alkaloid is found by multiplying the number of cubic centimeters of volumetric acid consumed by a constant factor, depending upon the molecular weight of the individual alkaloid. These factors will be found on page 1725, under Tenth-Normal Sulphuric Acid V.S. (No. 154), and are used throughout the text without explanation. The factor in each case represents the weight in grammes of the alkaloid required to neutralize 1 Cc. of volumetric acid.

DETERMINATION OF THE OPTICAL ROTATION OF ORGANIC SUBSTANCES.

(U. S. P. 8TH REV.)

Many organic substances either liquid by nature or in solution in suitable solvents, when examined in a specially constructed polarizing apparatus or polaristrobometer, exhibit the property of circular polarization, or, in other words, are capable of rotating the plane of polarization of a ray of light either to the right or to the left. Such substances are termed "optically active," and when rotating to the right are designated as "dextro-rotatory" or "dextrogyrate," and when rotating to the left, as "levo-rotatory" or "levogyrate." Substances which do not possess this property of optical rotation are termed "optically inactive."

Among the substances recognized by the U. S. P. (8th Rev.), there are several, particularly certain essential or volatile oils, and related bodies, for which the determination of the angle of rotation of a ray of polarized light, or, in some cases, the proof of their optical inactivity, affords the most simple and positive evidence of their identity or purity.

The instruments used for this purpose vary somewhat in their construction. Those which are most generally adapted for the examination of the substances mentioned above are the Polaristrobometer of Wild, in which the optical activity of the substance is manifested by the appearance or disappearance of dark, parallel stripes, or the so-called "half-shadow" instrument of Laurent, in which the two sides of the field of vision are capable of becoming unequally illuminated. Both of the instruments permit the angle of rotation to be read off in degrees or fractions of a degree of a circle.

These optical determinations are best made in a dark room, and by means of homogeneous or monochromatic light, the latter being obtained by introducing into a non-luminous flame, on a loop of platinum wire, a small bead of fused sodium chloride. The light thus radiated corresponds with the line D of the solar spectrum.

Since the deviation of the plane of polarization either to the right or to the left of the zero point is directly proportional to the length of the column of liquid, it is important that the observations should be made with tubes of a definite length, such as 100, 50, or 25 Mm. The selection of the length of the tube to be employed is, however, usually dependent upon the depth of color of the liquid and the extent of its optical rotation.

The rotatory power of an optically active, liquid substance, observed with sodium light, and referred to the ideal density 1, and in a tube having a length of 1 decimeter (100 Mm.), is designated as its *specific rotatory power*. This is usually expressed by the term $[\alpha]_D$. Since, however, not only the density of an optically active liquid, but also its rotation, is influenced by the temperature, the specific rotation varies with the latter. In stating the specific rotation it is, therefore, necessary to indicate at what temperature the rotation and the density of the liquid have been determined. But for the same temperature the specific rotation of a pure, optically active liquid is always a constant number. The temperature used in the text of the U. S. P. (8th Rev.) is 25° C. (77° F.).

For calculating the specific rotatory power of an optically active liquid substance, or solution of an optically active solid, the following formulas are of general application:

$$\begin{array}{ll} \text{I. For liquid substances} & [\alpha]_D = \frac{100 \times a}{L \times d} \\ \text{II. For solutions of solids} & \left\{ \begin{array}{l} [\alpha]_D = \frac{10000 \times a}{L \times p \times d} \\ \text{or} \\ [\alpha]_D = \frac{10000 \times a}{L \times c} \end{array} \right. \end{array}$$

For calculating these formulas the determination of the following factors is necessary:

- α = the angle of rotation of the liquid or solid observed with sodium light.
 L = the length of the tube in millimeters.
 d = the density or specific gravity of the active liquid.
 p = the amount of active substance in 100 parts by weight of the solution.
 c = the number of grammes of active substance in 100 cubic centimeters of the solution.

ARTICLES EMPLOYED IN CHEMICAL TESTING AND TEST-SOLUTIONS OF THE BRITISH PHARMACOPOEIA.

The British test-solutions here given are used for determining the character of particular substances, whether isolated or in composition; thus enabling us to ascertain the identity of medicines, their purity or impurity, and the character of the foreign ingredients, which may be mixed with them accidentally, or with a view to adulteration.

Acetic Acid.—"The Acetic Acid of the British Pharmacopœia." *Br.*

Acetic Acid, Glacial.—"The Glacial Acetic Acid of the British Pharmacopœia." *Br.*

Albumen.—"The liquid white, separated from the yolk, of the egg of *Gallus Bankiva*, *var. domesticus*, *Temminck*." *Br.*

Alcohol, Absolute.—"The Absolute Alcohol of the British Pharmacopœia." *Br.*

Alcohol (90 per cent.). **Alcohol** (70 per cent.).—"The Alcohol (90 per cent.) and Alcohol (70 per cent.) of the British Pharmacopœia." *Br.*

Alum.—"The Alum of the British Pharmacopœia." *Br.*

Ammonium Molybdate.—"A nearly white crystalline salt, $(\text{NH}_4)_2\text{MoO}_4$." *Br.*

Ammonium Oxalate.—"Colorless crystals, $(\text{COONH}_4)_2 \cdot \text{H}_2\text{O}$, prepared by neutralizing oxalic acid with solution of ammonia." *Br.*

Ammonium Thiocyanate.—"A crystalline salt, NH_4SCN ." *Br.*

Amylic Alcohol.—"A liquid consisting principally of iso-primary amylic alcohol, $(\text{CH}_3)_2\text{CH} \cdot \text{CH}_2 \cdot \text{CH}_2\text{OH}$. It may be prepared by shaking commercial fusel oil with a saturated solution of common salt, separating the oily layer, submitting it to distillation, and collecting and reserving the portion which distils between 257° and 289° F. (125° and 142.8° C.)." *Br.*

Barium Chloride.—"Colorless crystals, $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$. Its solution should not give a precipitate with solution of ammonium hydrosulphide, and no residue should remain after adding excess of diluted sulphuric acid, filtering, and evaporating the filtrate to dryness in a platinum dish. Barium nitrate, Ba_2NO_3 , or barium acetate, $(\text{CH}_3\text{COO})_2\text{Ba}$, may be used in place of barium chloride, but each must respond to the foregoing tests." *Br.*

Barium Hydroxide.—"Colorless crystals, $\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$, prepared by mixing concentrated solutions of barium chloride and sodium hydroxide. The precipitate is purified by recrystallization from water. It should be entirely soluble in water, the resulting solution should give no precipitate with solution of ammonium hydrosulphide, and a very slight residue should remain after adding excess of diluted sulphuric acid, filtering, and evaporating the filtrate to dryness in a platinum dish." *Br.*

Benzol.—"The Benzol of the British Pharmacopœia." *Br.*

Benzolated Amylic Alcohol.—"Benzol, 3 parts by volume; Amylic Alcohol, 1 part by volume. Mix; decant from any deposited water." *Br.*

Bismuth Oxynitrate.—"The Bismuth Oxynitrate of the British Pharmacopœia." *Br.*

Borax.—"The Borax, $\text{Na}_2\text{B}_4\text{O}_7 \cdot 10\text{H}_2\text{O}$, of the British Pharmacopœia." *Br.*

Bromine.—"The Bromine of commerce." *Br.*

Cadmium Iodide.—"The pure crystals, CdI_2 , of commerce." *Br.*

Calcium Carbonate.—"The pure white marble, or calc-spar, of commerce." *Br.*

Calcium Hydroxide.—"The Calcium Hydroxide of the British Pharmacopœia." *Br.*

Calcium Oxide.—"The Lime of the British Pharmacopœia." *Br.*

Calcium Sulphate.—"Pure native calcium sulphate, $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$." *Br.*

Carbon Bisulphide.—"The Carbon Bisulphide of the British Pharmacopœia." *Br.*

Chloroform.—"The Chloroform of the British Pharmacopœia." *Br.*

Citric Acid.—"The Citric Acid of the British Pharmacopœia." *Br.*

Collodion.—"The Collodion of the British Pharmacopœia." *Br.*

Copper.—"The metal in foil, wire, or turnings." *Br.*

Copper Oxyacetate.—"The pure copper oxyacetate, or verdigris, of commerce." *Br.*

Copper Sulphate.—"The Copper Sulphate of the British Pharmacopœia." *Br.*

Ether.—"The Ether of the British Pharmacopœia." *Br.*

Ferric Chloride.—"The pure anhydrous ferric chloride of commerce." *Br.*

Ferrous Sulphate.—"The Ferrous Sulphate of the British Pharmacopœia." *Br.*

Glycerin.—"The Glycerin of the British Pharmacopœia." *Br.*

Hydrochloric Acid.—"The Hydrochloric Acid of the British Pharmacopœia." *Br.*

Hydrochloric Acid, Diluted.—"The Diluted Hydrochloric Acid of the British Pharmacopœia." *Br.*

Hydrochloric Acid, Gaseous.—"The dry gas, HCl, prepared by the interaction of sulphuric acid and common salt." *Br.*

Hydrogen Sulphide.—Synonym—*Sulphuretted Hydrogen*. "A gas prepared by the action of hydrochloric acid on ferrous sulphide. It will be sufficiently pure after passing through two wash-bottles each containing water. A solution of the gas in water may also be employed, but only if it smells strongly of the gas and yields an abundant black precipitate with solution of lead subacetate." *Br.*

Indigo.—"A blue pigment prepared from various species of *Indigofera*, *Linn.*" *Br.*

Iron.—"The Iron of the British Pharmacopœia." *Br.*

Isinglass.—"The swimming bladder, or sound, of various species of *Acipenser*, *Linn.*, prepared and cut into shreds." *Br.*

Lead Acetate.—"The Lead Acetate of the British Pharmacopœia." *Br.*

Lead Peroxide.—"The pure lead peroxide, PbO_2 , of commerce." *Br.*

Lime.—"The Lime of the British Pharmacopœia." *Br.*

Litmus.—"A blue pigment prepared from various species of *Roccella*, *DC.* Litmus is used in several forms. For example, Solution of Litmus [page 1733]; Blue Litmus Paper, made by impregnating unglazed white paper with a solution of litmus; and Red Litmus Paper, made by impregnating the paper with the solution reddened by the previous addition of a very minute quantity of sulphuric acid. Litmus may also be employed in the solid form." *Br.*

Manganese Peroxide.—"The powdered native peroxide, MnO_2 , pyrolusite." *Br.*

Methyl-Orange.—"Methyl-orange, $NaO \cdot SO_2 \cdot C_6H_4N : N \cdot C_6H_4N(CH_3)_2$, or helianthin, is prepared by the combination of diazobenzenesulphonic acid and dimethylaniline in an alkaline solution. Its warm aqueous solution should give no precipitate with an alkali or with solution of calcium chloride, but an orange-yellow precipitate with solution of lead subacetate." *Br.*

Microcosmic Salt.—"The salt, $NaNH_4HPO_4 \cdot 4H_2O$, of commerce." *Br.*

Milk of Lime.—"Lime, 100 grammes; Distilled water, 200 cubic centimetres. Mix." *Br.*

Morphinated Water.—"Prepared by digesting pure morphine in Chloroform Water for seven days at a temperature of $60^\circ F.$ ($15.5^\circ C.$), with occasional agitation, so as to obtain a saturated solution of the alkaloid, and filtering from the undissolved morphine." *Br.*

Morphine.—"The precipitate obtained on adding solution of ammonia, in slight excess, to a solution of a pure morphine salt in water, the precipitate being washed with water until free from ammonium salt." *Br.*

Mucilage of Gum Acacia.—"The Mucilage of Gum Acacia of the British Pharmacopœia." *Br.*

Mucilage of Starch.—"Triturate 1 gramme of Starch with a small quantity of Distilled Water to form a smooth paste; add more Distilled Water, gradually, to produce 50 cubic centimetres of mixture; boil for a few minutes, constantly stirring; cool. Mucilage of Starch should be recently prepared." *Br.*

Nitric Acid.—"The Nitric Acid of the British Pharmacopœia." *Br.*

Nitric Acid, Diluted.—"The Diluted Nitric Acid of the British Pharmacopœia." *Br.*

Nitric Acid, Fuming.—"Nitric Acid of specific gravity 1.5." *Br.*

Oil of Turpentine.—"The Oil of Turpentine of the British Pharmacopœia." *Br.*

Olive Oil.—"The Olive Oil of the British Pharmacopœia." *Br.*

Petroleum Spirit.—Synonym—*Petroleum Ether*. "A colorless, very volatile, and highly inflammable liquid obtained from petroleum, and consisting of a mixture of the lower members of the paraffin series of hydrocarbons. Boiling point 122° to $140^\circ F.$ (50° to $60^\circ C.$). Specific gravity 0.670 to 0.700." *Br.*

Phenol.—"The Phenol of the British Pharmacopœia." *Br.*

Phenol-Phthalein.—"A crystalline substance produced by interaction of phenol and phthalic

anhydride. $\begin{matrix} & C_6H_4.OH \\ & | \\ C & \begin{cases} C_6H_4.OH \\ C_6H_4.CO \\ O \end{cases} \end{matrix}$ *Br.*

Picric Acid.—"Trinitrophenol, $C_6H_2(NO_2)_3OH$, obtained by the action of nitric acid on phenol." *Br.*

Potassium Bichromate.—"The Potassium Bichromate of the British Pharmacopœia." *Br.*

Potassium Chlorate.—"The Potassium Chlorate of the British Pharmacopœia." *Br.*

Potassium Chromate.—"The pure, neutral, yellow crystals, K_2CrO_4 , of commerce." *Br.*

Potassium Cyanide.—"The commercial salt, containing at least 90 per cent. of potassium cyanide, KCN." *Br.*

Potassium Ferricyanide.—"The red crystalline salt, $K_3FeC_6N_{12}$. Its aqueous solution should give no precipitate or blue coloration with a dilute solution of a pure ferric salt." *Br.*

Potassium Ferrocyanide.—"The yellow crystalline salt, $K_4FeC_6N_6 \cdot 3H_2O$, prepared by fusing together potassium carbonate, nitrogenous organic matter, and iron." *Br.*

Potassium Hydrogen Sulphite.—Synonym—*Acid Potassium Sulphite*. "The commercial salt, $KHSO_3$." *Br.*

Potassium Hydroxide.—"The Caustic Potash of the British Pharmacopœia." *Br.*

Potassium Iodide.—"The Potassium Iodide of the British Pharmacopœia." *Br.*

Potassium Permanganate.—"The Potassium Permanganate of the British Pharmacopœia." *Br.*

Potassium Sulphate.—"The Potassium Sulphate of the British Pharmacopœia." *Br.*

- Powdered Talc.**—"A natural magnesium silicate, powdered, and purified by boiling with diluted hydrochloric acid, washing with distilled water until neutral to litmus, and drying." *Br.*
- Sodium Acetate.**—"The pure commercial salt, $\text{CH}_3\text{COONa} \cdot 3\text{H}_2\text{O}$." *Br.*
- Sodium Arsenate.**—"The Sodium Arsenate of the British Pharmacopœia." *Br.*
- Sodium Bicarbonate.**—"The Sodium Bicarbonate of the British Pharmacopœia." *Br.*
- Sodium Carbonate.**—"The Sodium Carbonate of the British Pharmacopœia." *Br.*
- Sodium Chloride.**—"The Sodium Chloride of the British Pharmacopœia." *Br.*
- Sodium Hydrogen Sulphite.**—Synonym—*Acid Sodium Sulphite*. "The commercial salt, NaHSO_3 ." *Br.*
- Sodium Hydroxide.**—"The sodium hydroxide, sodium hydrate, or 'caustic soda,' of commerce, occurs in hard grayish-white rods or cakes, deliquescent, very alkaline and corrosive. It affords the reactions characteristic of sodium. It usually contains as impurities alumina, carbonates, chlorides, phosphates, silicates, and sulphates. A clear solution of caustic soda may be used, instead of a solution of Purified Sodium Hydroxide, in all analytical operations in which the foregoing impurities would not vitiate the result. Purified Sodium Hydroxide may be obtained by dissolving caustic soda in ethylic alcohol, filtering the solution, evaporating it to dryness in a silver dish, occasionally adding distilled water during the evaporation. The residue is Purified Sodium Hydroxide. It should yield no characteristic reaction with the tests for phosphates or sulphates, and not more than the slightest reactions with the tests for carbonates. It is not quite free from alumina. Pure Sodium Hydroxide may be prepared by the interaction of pure barium hydroxide and sodium sulphate, or by the interaction of pure sodium and water. A solution of Pure Sodium Hydroxide is required only in testing for small quantities of aluminium." *Br.*
- Sodium Nitrite.**—"The Sodium Nitrite of the British Pharmacopœia." *Br.*
- Sodium Potassium Tartrate.**—"The Sodium Potassium Tartrate of the British Pharmacopœia." *Br.*
- Sodium Sulphate.**—"The Sodium Sulphate of the British Pharmacopœia." *Br.*
- Sodium Sulphite.**—"The Sodium Sulphite of the British Pharmacopœia." *Br.*
- Sodium Thio-sulphate.**—Synonym—*Sodium Hyposulphite*. "The crystalline salt, $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O}$. 2.4644 grammes should decolorize 100 cubic centimetres of the volumetric solution of iodine." *Br.*
- Sulphur.**—"The Sublimed Sulphur of the British Pharmacopœia." *Br.*
- Sulphuric Acid.**—"The Sulphuric Acid of the British Pharmacopœia." *Br.*
- Sulphuric Acid, Diluted.**—"The Diluted Sulphuric Acid of the British Pharmacopœia." *Br.*
- Tartaric Acid.**—"The Tartaric Acid of the British Pharmacopœia." *Br.*
- Test Papers.**—"See 'Litmus' and 'Turmeric.'" *Br.*
- Tin.**—"Tin, granulated by letting drops of it in the molten state fall into water. It should yield no reactions with the tests for lead, copper, iron, or zinc." *Br.*
- Turmeric.**—"The dried rhizome of *Curcuma longa*, *Linn.* Turmeric is commonly used in the form of tincture prepared from the bruised rhizome, in the proportion of 1 gramme to 6 cubic centimetres of Alcohol (90 per cent.) by the process of maceration or in the form of paper prepared by steeping unglazed white paper in the tincture and drying." *Br.*
- Uranium Nitrate.**—"The crystals of pure uranium nitrate of commerce." *Br.*
- Water.**—"The Distilled Water of the British Pharmacopœia." *Br.*
- Zinc.**—"The laminated or granulated metal. It should be entirely dissolved by diluted hydrochloric acid. The solution should yield no characteristic reaction with the tests for lead, copper, cadmium, arsenium, tin, and iron." *Br.*

TEST-SOLUTIONS. *Br.*

- Solution of Albumen.**—"Albumen, 2 cubic centimetres; Distilled Water, 8 cubic centimetres, or a sufficient quantity. Mix by trituration in a mortar, and filter through clean tow first moistened with Distilled Water. Solution of Albumen must be recently prepared. The strength of the Solution may be adjusted to suit particular requirements." *Br.*
- Solution of Ammonia.**—"The Solution of Ammonia of the British Pharmacopœia." *Br.*
- Solution of Ammonia, Strong.**—"The Strong Solution of Ammonia of the British Pharmacopœia." *Br.*
- Solution of Ammonium Acetate.**—"The Solution of Ammonium Acetate of the British Pharmacopœia." *Br.*
- Solution of Ammonium Carbonate.**—"Ammonium Carbonate, in small pieces, 10 grammes; Solution of Ammonia, 15 cubic centimetres; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*
- Solution of Ammonium Chloride.**—"Ammonium Chloride, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*
- Solution of Ammonium Chloride (Nessler's).**—"Ammonium Chloride, 3.15 grammes; Distilled Water, recently boiled, and free from ammonia, sufficient to produce 1000 cubic centimetres. Dissolve." *Br.*
- Solution of Ammonium Citrate.**—"The Solution of Ammonium Citrate of the British Pharmacopœia." *Br.*
- Solution of Ammonium Hydrosulphide.**—"Saturate one hundred and twenty cubic centimetres of Solution of Ammonia with washed Hydrogen Sulphide; add eighty cubic centimetres of Solution of Ammonia. The Solution should be freshly prepared." *Br.*

Solution of Ammonium Molybdate.—"Ammonium Molybdate, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Ammonium Oxalate.—"Ammonium Oxalate, 5 grammes; Distilled Water, warm, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Ammonium Thiocyanate.—"Ammonium Thiocyanate, 5 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Auric Chloride.—"Pure Gold of commerce, in leaf, 1 gramme; Nitric Acid, 1.5 cubic centimetres; Hydrochloric Acid, 7 cubic centimetres; Distilled Water, a sufficient quantity. Place the Gold in a flask with the Nitric Acid and six cubic centimetres of the Hydrochloric Acid, first mixed with four cubic centimetres of the Distilled Water, and digest until it is dissolved. Add one cubic centimetre of Hydrochloric Acid. Evaporate in a basin at a temperature not exceeding 212° F. (100° C.) until acid vapors cease to be given off. Dissolve the auric chloride thus obtained in fifty cubic centimetres of Distilled Water." *Br.*

Solution of Barium Chloride.—"Barium Chloride, in crystals, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Barium Hydroxide.—"Barium Hydroxide, 10 grammes; Distilled Water, recently boiled, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Boric Acid.—"Boric Acid, 5 grammes; Alcohol (90 per cent.), sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Bromine.—"Bromine, 1 cubic centimetre; Distilled Water, sufficient to produce 150 cubic centimetres. Place the Bromine in a bottle furnished with a well-fitting stopper, and pour in the Distilled Water; shake several times. Keep the Solution in a dark place." *Br.*

Solution of Cadmium Iodide.—"Cadmium Iodide, 5 grammes; Distilled Water, sufficient to produce 100 cubic centimetres. Dissolve and filter." *Br.*

Solution of Calcium Chloride.—"Calcium Chloride, fused, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Calcium Sulphate.—"Calcium Sulphate, 2.5 grammes; Distilled Water, 200 cubic centimetres. Rub the Calcium Sulphate in a porcelain mortar for a few minutes with twenty cubic centimetres of the Distilled Water; shake the mixture thus obtained with the rest of the Distilled Water; set aside; filter." *Br.*

Solution of Chlorinated Soda.—"The Solution of Chlorinated Soda of the British Pharmacopœia." *Br.*

Solution of Chlorine.—"Produced by saturating Distilled Water with chlorine. The chlorine may be obtained by the interaction of Hydrochloric Acid and Manganese Peroxide, and should be purified by passing through a small quantity of water contained in a wash-bottle. The solution should be recently prepared." *Br.*

Solution of Chromic Acid.—"The Solution of Chromic Acid of the British Pharmacopœia." *Br.*

Solution of Copper Acetate.—"Copper Oxyacetate, in fine powder, 20 grammes; Acetic Acid, 40 cubic centimetres; Distilled Water, sufficient to produce 200 cubic centimetres. Dilute the Acetic Acid with twenty cubic centimetres of the Distilled Water; digest the Copper Oxyacetate in the mixture at a temperature not exceeding 212° F. (100° C.), with repeated stirring; continue heating until a dry residue is obtained. Digest the product in one hundred and sixty cubic centimetres of Boiling Distilled Water; make up the required volume with Distilled Water; filter." *Br.*

Solution of Copper Ammonio-Sulphate.—"Copper Sulphate, in crystals, 10 grammes; Solution of Ammonia, a sufficient quantity; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve the Copper Sulphate in one hundred and sixty cubic centimetres of the Distilled Water, and cautiously add the Solution of Ammonia to the liquid until the precipitate first formed is nearly dissolved; filter the product; finally make up the required volume with Distilled Water. A concentrated solution may be prepared by using a smaller quantity of distilled water." *Br.*

Solution of Copper Sulphate.—"Copper Sulphate, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve, and filter if necessary." *Br.*

Solution of Ferric Chloride.—"See 'Test-Solution of Ferric Chloride' [page 1734]." *Br.*

Solution of Ferric Sulphate.—"The Solution of Ferric Sulphate of the British Pharmacopœia." *Br.*

Solution of Ferrous Sulphate.—"Ferrous Sulphate, 4 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter. The Solution of Ferrous Sulphate should be recently prepared." *Br.*

Solution of Hydrogen Peroxide.—"The Solution of Hydrogen Peroxide of the British Pharmacopœia." *Br.*

Solution of Indigo Sulphate.—"Indigo, dry and in fine powder, 0.2 gramme; Sulphuric Acid, 200 cubic centimetres. Mix the Indigo with two cubic centimetres of the Sulphuric Acid in a small test-tube, and heat in boiling water for an hour; pour the product into the remainder of the acid; shake the mixture; decant the clear liquid." *Br.*

Solution of Iodine.—"The Volumetric Solution of Iodine [page 1738]." *Br.*

Solution of Isinglass.—"Isinglass, in shreds, 4 grammes; Distilled Water, warm, sufficient to produce 200 cubic centimetres. Mix, and digest for half an hour on a water-bath with repeated shaking, and filter through clean moistened tow. Solution of Isinglass must be recently prepared." *Br.*

Solution of Lead Acetate.—"Lead Acetate, 20 grammes; Distilled Water, recently boiled, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Lead Subacetate.—"The Strong Solution of Lead Subacetate of the British Pharmacopœia; or the same, more or less diluted." *Br.*

Solution of Lime.—Synonym—*Solution of Calcium Hydroxide.* "The Solution of Lime of the British Pharmacopœia." *Br.*

Solution of Litmus.—"Litmus, in powder, 20 grammes; Alcohol (90 per cent.), 200 cubic centimetres; Distilled Water, 200 cubic centimetres. Boil the Litmus with eighty cubic centimetres of the Alcohol for one hour; pour away the clear liquid; repeat this operation with sixty cubic centimetres of the Alcohol; and a third time with the remainder of the Alcohol. Digest the washed Litmus in the Distilled Water, and filter." *Br.*

Solution of Magnesium Ammonio-Sulphate.—"Magnesium Sulphate, 20 grammes; Ammonium Chloride, 40 grammes; Solution of Ammonia, 84 cubic centimetres; Distilled Water, 160 cubic centimetres. Dissolve the Magnesium Sulphate and Ammonium Chloride in the Distilled Water; add the Solution of Ammonia, and set the mixture aside for a few days in a well-closed bottle; decant and filter." *Br.*

Solution of Magnesium Sulphate.—"Magnesium Sulphate, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Mercuric Chloride.—"See 'Test-Solution of Mercuric Chloride' [page 1734]." *Br.*

Solution of Mercurous Nitrate.—"Mercury, 2 grammes; Nitric Acid, 1 cubic centimetre; Distilled Water, a sufficient quantity. To the Mercury, in a small dish, add one cubic centimetre of Distilled Water and the Nitric Acid, and set the whole aside for twenty-four hours in a cool dark place; drain the resulting crystals; dissolve them in two hundred cubic centimetres of Distilled Water." *Br.*

Solution of Methyl Orange.—"Methyl Orange, 0.4 gramme; Alcohol (90 per cent.), 50 cubic centimetres; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve." *Br.*

Solution of Phenol-Phthalein.—"Phenol-phthalein, 0.4 gramme; Alcohol (90 per cent.), 120 cubic centimetres; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve. The Solution should be colorless." *Br.*

Solution of Picric Acid.—"Picric Acid, 1 gramme; Distilled Water, sufficient to produce 150 cubic centimetres. Dissolve." *Br.*

Solution of Platinic Chloride.—"Platinum foil of commerce, 10 grammes; Hydrochloric Acid, 60 cubic centimetres; Nitric Acid, 10 cubic centimetres; Distilled Water, sufficient to produce 200 cubic centimetres. Heat the Platinum foil with the Hydrochloric Acid to about 176° F. (80° C.); add the Nitric Acid very gradually; evaporate the solution to dryness on a water-bath; moisten the residue with a few drops of Hydrochloric Acid; again evaporate to dryness; dissolve the residue in sufficient Distilled Water to produce two hundred cubic centimetres of the Solution." *Br.*

Solution of Potassio-Cupric Tartrate.—Synonym—*Fehling's Solution.*

No. 1. Copper Sulphate, in crystals, 34.64 grammes; Sulphuric Acid, 0.5 cubic centimetre; Distilled Water, sufficient to produce 500 cubic centimetres. Dissolve.

No. 2. Sodium Potassium Tartrate, 176 grammes; Sodium Hydroxide, 77 grammes; Distilled Water, sufficient to produce 500 cubic centimetres. Dissolve. Mix equal volumes of the solutions No. 1 and No. 2 at the time of using." *Br.*

Solution of Potassio-Mercuric Iodide.—Synonym—*Nessler's Reagent.* "Potassium Iodide, 7 grammes; Mercuric Chloride, a sufficient quantity; Sodium Hydroxide, 24 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve the Potassium Iodide and two and a half grammes of Mercuric Chloride in one hundred and sixty cubic centimetres of Distilled Water; to this liquid add a cold saturated aqueous solution of Mercuric Chloride, with constant stirring, until a slight red precipitate remains; add the Sodium Hydroxide; when the latter has dissolved add a little more of the aqueous solution of Mercuric Chloride, and make up to the required volume with Distilled Water." *Br.*

Solution of Potassium Acetate.—"Potassium Acetate, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Potassium Acid Tartrate.—"Digest excess of Acid Potassium Tartrate in Distilled Water; filter." *Br.*

Solution of Potassium Carbonate.—"Potassium Carbonate, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Potassium Chromate.—"Potassium Chromate, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Potassium Cyanide.—"Potassium Cyanide, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Potassium Ferricyanide.—"Potassium Ferricyanide, in crystals, 10 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter. This Solution should be freshly prepared." *Br.*

Solution of Potassium Ferrocyanide.—"Potassium Ferrocyanide, in crystals, 10 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Potassium Hydroxide.—"The Solution of Potash of the British Pharmacopœia." *Br.*

Solution of Potassium Hydroxide, Alcoholic.—"Potassium Hydroxide, 20 grammes; Alcohol (90 per cent.), sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Potassium Iodide.—"Potassium Iodide, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Potassium Permanganate.—"The Solution of Potassium Permanganate of the British Pharmacopœia." *Br.*

Solution of Pyroxylin.—"The Collodion of the British Pharmacopœia." *Br.*

Solution of Silver Ammonio-Nitrate.—"Silver Nitrate, in crystals, 5 grammes; Solution of Ammonia, 10 cubic centimetres, or a sufficient quantity; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve the Silver Nitrate in one hundred and sixty cubic centimetres of the Distilled Water, and cautiously add the Solution of Ammonia to the liquid until the precipitate first formed is nearly dissolved; set aside; decant; finally make up to the required volume with Distilled Water." *Br.*

Solution of Silver Nitrate.—"Silver Nitrate, 10 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve." *Br.*

Solution of Sodium Acetate.—"Sodium Acetate, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Sodium Carbonate.—"Sodium Carbonate, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Sodium Hydroxide.—"Purified Sodium Hydroxide, 40 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Sodium Phosphate.—"Sodium Phosphate, in crystals, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Sodium Sulphate.—"Sodium Sulphate, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

Solution of Stannous Chloride.—"Tin, granulated, 40 grammes; Hydrochloric Acid, 120 cubic centimetres; Distilled Water, sufficient to produce 200 cubic centimetres. Dilute the Acid in a flask with forty cubic centimetres of the Distilled Water, and, having added the Tin, apply heat gently until gas ceases to be evolved; make up to the required volume with Distilled Water, allowing the undissolved Tin to remain in the Solution." *Br.*

Solution of Sulphurous Acid.—"The Sulphurous Acid of the British Pharmacopœia." *Br.*

Solution of Tannic Acid.—"Tannic Acid, 20 grammes; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve. Solution of Tannic Acid should be freshly prepared." *Br.*

Solution of Tartarated Antimony.—"Tartarated Antimony, 10 grammes; Distilled Water, boiling, sufficient to produce 200 cubic centimetres. Dissolve and filter. Solution of Tartarated Antimony should be freshly prepared." *Br.*

Solution of Tartaric Acid.—"Tartaric Acid, in crystals, 25 grammes; Alcohol (90 per cent.), 50 cubic centimetres; Distilled Water, sufficient to produce 200 cubic centimetres. Dissolve the Tartaric Acid in one hundred and thirty cubic centimetres of the Distilled Water; add the Alcohol; make up to the required volume with Distilled Water." *Br.*

Solution of Uranium Nitrate.—"Uranium Nitrate, 10 grammes; Distilled Water, sufficient to produce 200 cubic centimetres." *Br.*

Test-Solution of Ferric Chloride.—"Dissolve 10 grammes of commercial anhydrous Ferric Chloride in sufficient Distilled Water to produce 200 cubic centimetres of solution. Filter if necessary." *Br.*

Test-Solution of Mercuric Chloride.—"Mercuric Chloride, 10 grammes; Distilled Water, boiling, sufficient to produce 200 cubic centimetres. Dissolve and filter." *Br.*

TESTS FOR SUBSTANCES MENTIONED IN THE TEXT OF THE BRITISH PHARMACOPŒIA.

Acetates.—"Neutral acetates are decomposed by heat, yielding vapors which possess a characteristic acetous odor. Hydrogen acetate and ethyl acetate have characteristic odors. Acetates when warmed with sulphuric acid yield vapors of hydrogen acetate; or, when warmed with sulphuric acid and a small quantity of alcohol (90 per cent.), yield ethyl acetate. Test-solution of ferric chloride affords a deep red coloration with neutral or faintly acid acetates, and the resulting liquid on boiling yields a reddish-brown precipitate. On adding hydrochloric acid the red solution turns yellow. On adding test-solution of mercuric chloride the red color is not discharged (distinction from thiocyanates). Dry acetates heated with (a very minute proportion of) arsenious anhydride yield (the highly poisonous) cacodyl oxide, recognizable by its characteristic smell." *Br.*

Aluminium.—"Solution of ammonia or solution of ammonium hydrosulphide affords a white gelatinous precipitate, soluble in hydrochloric acid, in acetic acid, and in solution of potassium hydroxide or solution of sodium hydroxide, but nearly insoluble in solution of ammonia and in solutions of ammonium salts, and quite insoluble when the solutions are boiled. Solution of ammonium oxalate causes no precipitate." *Br.*

Ammonium Salts.—"Ammonium salts volatilize when strongly heated, generally without residue. When heated with solution of potassium hydroxide, or with solution of sodium hydroxide, ammonium salts evolve ammonia, recognizable by its odor. Solution of platinic chloride affords with ammonium salts acidulated with hydrochloric acid a yellow crystalline precipitate, especially in the presence of alcohol. On ignition, this precipitate leaves a residue of platinum only. A concentrated solution of tartaric acid produces in concentrated solutions of ammonium salts a white crystalline precipitate, especially in the presence of much alcohol. Solution of potassium-mercuric iodide affords a brown precipitate, or a reddish-brown coloration, or, in excessively dilute solutions of ammonium salts, a yellowish tinge." *Br.*

Antimony.—"Hydrogen sulphide yields, in slightly acid solutions, an orange-colored precipitate, soluble in solution of potassium hydroxide, in ammonium hydrosulphide, and in the strongest hydrochloric acid with evolution of hydrogen sulphide, but almost insoluble in solution of the official Ammonium Carbonate and in solution of potassium hydrogen sulphite. Hydrogen, generated by the interaction

of zinc and diluted sulphuric acid, partially converts antimony compounds into hydrogen antimonide. A cold porcelain tile held in the flame of this gas acquires a dark metallic deposit, which is not appreciably dissolved by solution of chlorinated soda. The gas, when passed into solution of silver nitrate, causes a black precipitate containing antimony and silver, and on the cautious addition of solution of ammonia the supernatant liquid yields no yellow precipitate. If one end of a strip or rod of zinc be allowed to rest on a platinum capsule containing the acidulated antimony solution, the other end being in the liquid, hydrogen antimonide is not evolved, but the antimony is precipitated on the platinum as a black, adherent, non-granular stain, insoluble in hydrochloric acid. Copper foil precipitates antimony from solutions, and the antimony may be volatilized by heat, condensing as a white amorphous sublimate of oxides of antimony near to the copper." *Br.*

Arsenium.—"Hydrogen sulphide affords in solutions containing hydrochloric acid a yellow precipitate, soluble in solution of potassium hydroxide, potassium carbonate, ammonium hydrosulphide, and potassium hydrogen sulphite, and in solution of the official Ammonium Carbonate, but reprecipitated on addition of hydrochloric acid. The precipitate is insoluble in the strongest hydrochloric acid.

Nascent hydrogen, generated by the interaction of zinc and diluted sulphuric acid, converts arsenium compounds into hydrogen arsenide. A cold porcelain tile held in the flame of this gas acquires a dark metallic deposit, which is readily dissolved by solution of chlorinated soda. The gas, when passed into excess of solution of silver nitrate, causes a black precipitate of silver, and the cautious addition of solution of ammonia to the supernatant liquid causes a yellow precipitate. Hydrogen, generated by the interaction of zinc and solution of potassium hydroxide or sodium hydroxide, converts arsenium compounds into hydrogen arsenide. This gas gives a black stain to filtering paper soaked with solution of silver nitrate and placed as a cap over the tube in which the test is being performed. Hydrogen antimonide is not evolved from antimony compounds under similar circumstances. The operation should be performed in an atmosphere which is free from hydrogen sulphide. Stannous chloride dissolved in a large excess of hydrochloric acid gives on boiling with a solution containing arsenium a brownish-black precipitate. Bright copper foil precipitates arsenium from solutions acidulated by hydrochloric acid, and the arsenium may be volatilized by heat in an open tube, when it condenses, at some distance from the copper, as a white sublimate of characteristic octahedral crystals. *Arsenites.*—Solutions of arsenites yield a yellow precipitate with solution of silver ammonio-nitrate. *Arsenates.*—Solutions of arsenates yield a reddish-chocolate precipitate with solution of silver ammonio-nitrate. Solution of magnesium ammonio-sulphate affords a white crystalline precipitate." *Br.*

Bismuth.—"Hydrogen sulphide affords a brownish-black precipitate, insoluble in solution of potassium hydroxide, of potassium cyanide, in diluted hydrochloric acid, and in ammonium hydrosulphide, but decomposed and dissolved by boiling nitric acid. Solution of potassium hydroxide, sodium hydroxide, or ammonia, except in the presence of citrates, yields a white precipitate insoluble in excess of the precipitant. Dilute solution of sodium chloride in large excess gives in solutions which are not too acid a white precipitate, insoluble in tartaric acid. Solution of potassium chromate gives a yellow precipitate, soluble in dilute nitric acid, insoluble in solution of potassium hydroxide. Stannous chloride dissolved in a concentrated solution of potassium hydroxide gives a black precipitate when added in excess to a solution containing bismuth. Diluted sulphuric acid does not precipitate bismuth salts." *Br.*

Bromates.—"From bromates solution of sulphurous acid liberates bromine, recognizable by its odor and appearance. After ignition with charcoal bromates are converted into bromides, and the latter yield their characteristic reactions." *Br.*

Bromides or Hydrobromides.—"Solution of silver nitrate gives a yellowish curdy precipitate, readily soluble in solution of potassium cyanide, somewhat soluble in strong but almost insoluble in weak solution of ammonia, and insoluble in nitric acid. Solution of sodium nitrite with the addition of diluted hydrochloric acid does not liberate bromine from a bromide. Solution of chlorine liberates bromine soluble in two or three drops of carbon bisulphide or of chloroform, and forming a reddish solution. Bromine is liberated when a bromide is heated with sulphuric acid and manganese peroxide, lead peroxide, or potassium bichromate, the vapor giving an orange-yellow color to filter-paper soaked in mucilage of starch. In testing for bromides in the presence of iodides, all iodine should first be removed by boiling the aqueous solution with excess of lead peroxide." *Br.*

Cadmium.—"Hydrogen sulphide yields a yellow precipitate, insoluble in cold dilute hydrochloric acid, in solutions of ammonium hydrosulphide, of potassium hydroxide, and of potassium cyanide, but soluble in nitric acid, in hot diluted hydrochloric acid, and in hot diluted sulphuric acid. Solution of potassium hydroxide and solution of sodium hydroxide afford white precipitates insoluble in excess. Solution of ammonia gives a white precipitate readily soluble in excess." *Br.*

Calcium.—"Solution of ammonium carbonate yields a white precipitate, which, after boiling well and setting aside the mixture, is insoluble in solution of ammonium chloride. Solution of ammonium oxalate gives a white precipitate, soluble in hydrochloric acid, but insoluble in acetic acid. Solution of potassium chromate gives no precipitate." *Br.*

Carbonates and Bicarbonates.—"Dilute acids cause an effervescence of carbonic anhydride, which is odorless, and causes a white precipitate in solution of lime, or in solution of barium hydroxide. Soluble carbonates afford a brownish-red precipitate with test-solution of mercuric chloride, bicarbonates a whitish precipitate; the former yield a white precipitate with a cold solution of magnesium sulphate, the latter do not." *Br.*

Chlorides or Hydrochlorides.—"Solution of silver nitrate affords a white curdy precipitate, soluble in solution of ammonia or solution of potassium cyanide, but insoluble in nitric acid. A solid chloride or hydrochloride, when subjected to distillation with sulphuric acid and potassium bichromate, yields a reddish-brown distillate, which is decomposed by water. The resulting solution when nearly neutralized gives a yellow precipitate with solution of lead acetate or solution of barium chloride, and a mixed red and white precipitate with solution of silver nitrate, of which the red portion is dissolved by nitric acid,

and both portions by solution of ammonia. Heated with manganese peroxide and sulphuric acid, chlorides or hydrochlorides yield chlorine, recognizable by its odor and by giving a blue color with solution of potassium iodide and mucilage of starch." *Br.*

Citrates.—"Citrates become charred when heated. Solution of calcium chloride added in excess affords, when boiled with a neutral solution of a citrate, a white precipitate, insoluble in solution of potassium hydroxide, but soluble in solution of ammonium chloride and in solutions of alkaline citrates. Solution of silver nitrate causes in solutions of neutral citrates a white precipitate soluble in solution of ammonia. A mirror is not formed on the sides of the tube when the ammoniacal solution is warmed (distinction from tartrates)." *Br.*

Copper.—"Hydrogen sulphide or solution of ammonium hydrosulphide yields in solutions which are not strongly acid a brownish-black precipitate, insoluble in diluted hydrochloric acid and in solution of potassium hydroxide, almost insoluble in solution of ammonium hydrosulphide, but decomposed and dissolved by boiling nitric acid, and when freshly precipitated soluble in solution of potassium cyanide. Solution of potassium hydroxide gives a bulky light blue precipitate which becomes brownish black on boiling. The light blue precipitate is soluble in a very large excess of a concentrated solution of potassium hydroxide, forming a blue solution. In the presence of soluble tartrates or citrates the light blue precipitate dissolves at once in the solution of potassium hydroxide, yielding a blue liquid which is not affected on boiling. Dextrose and other sugars act similarly, but the resulting solution, on warming, affords a yellowish-red to bright red precipitate. In the presence of non-volatile organic acids solution of potassium hydroxide produces no precipitate, but on the addition of the reagent the solution becomes deep blue. Solution of ammonia or of ammonium carbonate added in small quantity to a neutral solution of a copper salt gives a greenish-blue precipitate which readily dissolves in excess of solution of ammonia, forming a deep blue solution. This blue coloration is perceptible in highly dilute solutions. Solution of potassium ferrocyanide gives a reddish-brown precipitate, or in very dilute solutions a reddish-brown coloration, unaffected by dilute acids but decomposed by solution of potassium hydroxide. Metallic iron receives a reddish coating of copper when placed in a solution of a copper salt." *Br.*

Cyanides.—"Solution of silver nitrate affords a white curdy precipitate, soluble in solution of potassium cyanide, in solution of ammonia, and in boiling concentrated nitric acid. If to a soluble cyanide be added a few drops of a mixed solution of ferrous and ferric salts, then of solution of sodium hydroxide, and lastly excess of hydrochloric acid, a precipitate of Prussian blue results. Insoluble cyanides decompose when heated, evolving cyanogen, which burns with a characteristic peach-colored flame." *Br.*

Hydrobromides.—See "Bromides," page 1735.

Hydrochlorides.—See "Chlorides," page 1735.

Iodates.—"Solution of silver nitrate gives a white crystalline precipitate, sparingly soluble in water and in dilute nitric acid, but readily dissolved by solution of ammonia. Solution of sulphurous acid when added to the ammoniacal solution gives a pale yellow precipitate. A mixed solution of potassium iodide and tartaric acid in a solution of an iodate yields iodine, which affords a blue color with mucilage of starch. Solution of barium chloride gives a white precipitate nearly insoluble in water and soluble with difficulty in diluted nitric acid. On the addition of mucilage of starch and solution of sulphurous acid a blue color is produced." *Br.*

Iodides.—"Solution of silver nitrate affords a curdy yellow precipitate, insoluble in nitric acid and almost insoluble in solution of ammonia, but soluble in solution of potassium cyanide. Solution of mercurous nitrate produces a green precipitate, insoluble in diluted nitric acid, soluble in solution of potassium iodide. Test-solution of mercuric chloride yields a scarlet precipitate, slightly soluble in excess of this reagent, and very soluble in solution of potassium iodide. Solution of lead acetate causes a yellow precipitate, soluble in diluted nitric acid and soluble in boiling water. From the latter solution the precipitate separates in golden crystalline scales as the solution cools. Solution of copper sulphate, mixed with the solution of ferrous sulphate or of sulphurous acid, affords a whitish precipitate, soluble in solution of ammonia, sparingly soluble in hydrochloric acid. A small quantity of solution of chlorine or bromine, or a solution of sodium nitrite and diluted hydrochloric acid, liberates iodine. A very minute quantity of free iodine produces an intense blue coloration with mucilage of starch. If liquid containing free iodine be shaken with carbon bisulphide, the iodine is dissolved by the carbon bisulphide and communicates a violet color to it." *Br.*

Iron.—"Reactions common to Ferrous and Ferric salts: Solution of ammonium hydrosulphide yields, in neutral solutions, a black precipitate soluble in cold diluted hydrochloric acid with evolution of hydrogen sulphide. Solution of potassium ferrocyanide gives a blue precipitate, or a white precipitate rapidly turning blue, insoluble in dilute hydrochloric acid, decomposed by solution of potassium hydroxide or by solution of sodium hydroxide.

Reactions characteristic of Ferrous salts: Hydrogen sulphide causes no precipitate in a slightly acid solution. Solution of potassium ferricyanide affords a dark blue precipitate, insoluble in dilute hydrochloric acid, decomposed by solution of potassium hydroxide or solution of sodium hydroxide. (Ferric salts give a reddish-brown coloration but no precipitate with this reagent.) Ferrous salts mixed with solution of potassium or sodium hydroxide give a dull green precipitate.

Reactions characteristic of Ferric salts: Hydrogen sulphide gives a white precipitate of sulphur. Solution of ammonium thiocyanate produces a blood-red coloration, which is discharged on the addition of test-solution of mercuric chloride. Solution of tannic acid yields a bluish-black coloration or precipitate with ferric salts, and, more slowly, with ferrous salts. Solution of potassium, sodium, or ammonium hydroxide causes a reddish-brown precipitate, soluble in solution of citric or tartaric acid, and not formed in the presence of citrates and tartrates." *Br.*

Lead.—"Hydrochloric acid affords, except in very weak solutions, a white precipitate soluble in boiling water. The aqueous solution as it cools deposits the lead chloride in the crystalline form. Hydrogen sulphide in not very strongly acid solutions yields a black precipitate insoluble in dilute hydrochloric acid, solution of potassium hydroxide, and solution of ammonium hydrosulphide. It is decom-

posed by boiling with diluted nitric acid, being partly converted into soluble lead nitrate and partly into white insoluble lead sulphate and sulphur. Diluted sulphuric acid causes a white precipitate almost insoluble in water, and still less soluble in dilute sulphuric acid and in alcohol, but soluble in solution of ammonium acetate. Solution of potassium chromate produces a yellow precipitate readily soluble in solution of potassium hydroxide, in strong, hot nitric acid, sparingly soluble in diluted nitric acid, insoluble in acetic acid. Solution of potassium hydroxide gives a white precipitate soluble in excess of the reagent, but insoluble in solution of ammonia." *Br.*

Magnesium.—"Solution of ammonium carbonate, in the presence of solution of ammonium chloride, affords no precipitate. Solution of sodium phosphate, or solution of sodium arsenate, in the presence of ammonium salts and solution of ammonia, yields a white crystalline precipitate. Solution of potassium, sodium, ammonium, barium, or calcium hydroxide causes a white precipitate, insoluble in excess of the reagent, but soluble in solution of ammonium chloride." *Br.*

Mercury.—"Reactions common to Mercurous and Mercuric salts: Hydrogen sulphide yields a black precipitate, insoluble in solution of ammonium hydrosulphide and in boiling diluted nitric acid. Copper foil immersed in a solution free from excess of nitric acid becomes coated with a deposit of mercury which on rubbing becomes bright, and from which the mercury may be volatilized by heat and obtained in globules. Solution of stannous chloride reduces mercuric salts, first to mercurous salts and then to metallic mercury.

Reactions characteristic of Mercurous salts: Hydrochloric acid affords a white precipitate insoluble in water, which is blackened by solution of ammonia. Solution of potassium or sodium hydroxide produces a black precipitate of mercurous oxide, and solution of ammonia a black precipitate of a mercurous-amido salt. Solution of potassium iodide gives a green precipitate soluble in excess of the precipitant.

Reactions characteristic of Mercuric salts: Solution of ammonia affords a white precipitate. Solutions of potassium or sodium hydroxide yield a yellow precipitate of mercuric oxide. Solution of potassium iodide produces a scarlet precipitate, soluble in excess of the precipitant, and in a considerable excess of the solution of the mercuric salt." *Br.*

Nitrates.—"Ferrous sulphate and sulphuric acid, when added to a solution of a nitrate in such a way that the acid forms a stratum below the aqueous solution, cause a purple or brown coloration at the junction of the two liquids. Nitrates liberate red fumes when warmed with sulphuric acid and copper. Nitrates discharge the color of solution of indigo sulphate containing excess of sulphuric acid, especially if the mixture is warmed." *Br.*

Nitrites.—"On the addition, to a solution of a nitrite, of a few drops of diluted sulphuric acid, solution of potassium iodide, and mucilage of starch, a blue color is produced. Diluted sulphuric acid affords red fumes. Solution of ferrous sulphate and acetic acid yield a deep brown color." *Br.*

Oxalates.—"Solution of calcium chloride affords a white precipitate, soluble in hydrochloric acid, but insoluble in acetic acid. Solution of silver nitrate yields a white precipitate, soluble in solution of ammonia and in diluted nitric acid. Most oxalates are on ignition converted into carbonates. Oxalates do not char when heated with sulphuric acid, but yield carbonic oxide and carbonic anhydride." *Br.*

Phosphates (Ortho-).—"Solution of silver ammonio-nitrate yields in solution of ortho-phosphates a light yellow precipitate readily soluble in solution of ammonia and in cold dilute nitric acid. Test-solution of ferric chloride, in the presence of ammonium acetate or other acetate, yields a whitish precipitate, insoluble in acetic acid. Solution of magnesium ammonio-sulphate affords a white crystalline precipitate. Excess of solution of ammonium molybdate, containing much nitric acid, produces, on warming, a yellow precipitate." *Br.*

Potassium.—"Solution of platinic chloride affords with moderately strong solutions of potassium chloride (or with other potassium salts if hydrochloric acid be present) a yellow crystalline precipitate, which, upon ignition, leaves a residue of potassium chloride and platinum. Potassium compounds moistened with hydrochloric acid communicate a violet coloration when introduced, on platinum wire, into the flame of a spirit lamp or Bunsen burner." *Br.*

Selenium and Tellurium.—"Selenium and Tellurium may occur in compounds of bismuth. To detect these elements, dissolve the compound in nitric acid, add solution of sodium chloride or ammonium chloride, and dilute freely with water. The filtrate from the precipitated oxychloride, mixed with excess of sodium sulphite, should give no precipitate or coloration even after twelve hours." *Br.*

Silica.—"Silica, after exposure to a red heat, is insoluble in acids, and is not dissolved in a bead of microcosmic salt when heated to fusion in the blow-pipe flame. The result of its fusion with alkalis is soluble in water, the solution yielding a gelatinous precipitate on the addition of hydrochloric acid." *Br.*

Silver.—"Hydrochloric acid and other chlorides afford a white curdy precipitate, soluble in solution of ammonia, but insoluble in nitric acid. Solution of potassium chromate, in the absence of chlorides, bromides, and iodides, affords a red precipitate." *Br.*

Sodium.—"Sodium compounds, moistened with hydrochloric acid, communicate a yellow coloration when introduced, on platinum wire, into the flame of a spirit lamp or Bunsen burner." *Br.*

Starch.—"When starch is boiled with water, the mixture, on cooling, affords a deep blue coloration on the addition of solution of iodine. When boiled for some minutes with water acidulated with hydrochloric acid, and then made alkaline with sodium hydroxide, a red precipitate is formed on further boiling after the addition of solution of potassium-cupric tartrate. The varieties of starch may be distinguished by their microscopical characters." *Br.*

Sulphates.—"Solution of barium chloride affords a white precipitate insoluble in hydrochloric acid." *Br.*

Sulphides.—"The official sulphides, hydrosulphides, and sulphurated compounds evolve hydrogen sulphide when boiled with strong hydrochloric acid. Sulphonal and thiocyanates do not evolve hydrogen

sulphide when treated in this way. If fused with sodium carbonate, mixed with a small proportion of potassium nitrate, they afford a mass which, when dissolved in water, responds to the tests for sulphates." *Br.*

Sulphites.—"Hydrochloric acid liberates sulphurous anhydride, a colorless gas with a pungent smell of burning sulphur. Hydrochloric acid and zinc being added, hydrogen sulphide, recognizable by its odor, is liberated. Sulphites decolorize solution of iodine." *Br.*

Tartrates.—"Tartrates become charred when heated. Solution of calcium chloride added in excess to a solution of a neutral tartrate affords a white granular precipitate, soluble, when fresh, in cold, moderately concentrated solution of potassium hydroxide, from which it is precipitated on boiling. It is also soluble in tartaric acid. Solution of silver nitrate yields a white precipitate, soluble in solution of ammonia and in nitric acid. The ammoniacal solution is reduced on heating, and deposits metallic silver as a mirror on the sides of the test-tube. A concentrated solution of potassium acetate gives a white precipitate in moderately concentrated solutions when acidulated with acetic acid and well stirred, and especially on the addition of alcohol (90 per cent.). If to the solution of tartaric acid in water, or of a tartrate acidulated with acetic acid, be added a drop of solution of ferrous sulphate, then a few drops of solution of hydrogen peroxide, and finally an excess of solution of potassium hydroxide, a purple or violet color will be produced." *Br.*

Tellurium.—See "Selenium," page 1737.

Thiosulphates.—"Hydrochloric acid gives a yellow precipitate and liberates sulphurous anhydride, recognizable by its odor. Hydrochloric acid and zinc liberate hydrogen sulphide. Thiosulphates decolorize solution of iodine." *Br.*

Tin.—"Metallic zinc placed in a solution of any tin salt acidulated with hydrochloric acid precipitates the whole of the tin in metallic scales or as a gray sponge. The metal, separated from the liquid, is soluble in boiling concentrated hydrochloric acid, and the solution, which contains stannous chloride, gives with test-solution of mercuric chloride a white precipitate of calomel, which becomes gray from separation of metallic mercury, if excess of tin salt is present." *Br.*

Zinc.—"Solution of ammonium hydrosulphide yields with neutral, and hydrogen sulphide with alkaline, solutions a white precipitate, soluble in hydrochloric acid, but insoluble in acetic acid. Solution of potassium hydroxide or of ammonia affords a white precipitate, soluble in excess of either reagent. Solution of potassium ferrocyanide produces a white precipitate, insoluble in diluted hydrochloric acid." *Br.*

TEST-SOLUTIONS FOR VOLUMETRIC ESTIMATIONS. *Br.*

"The following apparatus is required in the preparation and use of these solutions. 1. A glass flask which, when filled to a mark on the neck, contains 1000 grammes of distilled water at 60° F. (15.5° C.). This flask is described as the 'one-litre flask,' and is used in ordinary analytical operations to measure 1000 cubic centimetres, as it is customary for the sake of convenience to make the measurement of liquids with metric apparatus which has thus been graduated at 60° F. (15.5° C.). 2. A graduated cylindrical jar which, when filled to the zero mark at 60° F. (15.5° C.), contains 1000 grammes of distilled water, and is divided into 100 equal parts, each of which is taken as corresponding to 10 cubic centimetres. 3. A burette. A graduated tube which, when filled to the zero mark at 60° F. (15.5° C.), holds, within the graduated portion, 50 grammes of distilled water; the graduated portion is divided into 50 equal parts, each of which is taken as corresponding to 1 cubic centimetre, and each such division is subdivided into 10 equal parts. A standard Litre contains 1 kilogramme (1000 grammes) of distilled water at the temperature of maximum density (39.2° F. or 4° C.), and at the barometric pressure of 760 millimetres of mercury. One-thousandth part of a standard Litre (one millilitre) is, strictly speaking, equivalent to 1.00016 cubic centimetres, or one cubic centimetre to 0.99984 millilitre. Any litre-measure or other piece of volumetric apparatus not actually marked '60° F.' or '15.5° C.' is to be taken as having reference to the standard Litre graduated at 39.2° F. or 4° C. Volumetric solutions, before being used, should be shaken, in order that they may be throughout of uniform strength. They should also be preserved in stoppered bottles." *Br.*

Volumetric Solution of Iodine.—(Iodine, I = 125.9.) "Iodine, 12.59 grammes; Potassium Iodide, 18 grammes; Distilled Water, a sufficient quantity. The Iodine should be pure. It may be obtained pure by mixing the official 'Iodum' with one-fourth of its weight of dry potassium iodide, resubliming, and leaving the resulting crystals for a few hours under a glass shade placed over a dish containing concentrated sulphuric acid. Put the Iodine and the Potassium Iodide (which should be pure), with about 20 cubic centimetres of Distilled Water, into the one-litre flask; gently agitate until solution is complete; then dilute the solution with Distilled Water until it measures 1000 cubic centimetres. The strength of this Solution should be verified by the aid of pure arsenious anhydride, pure barium thiosulphate, or other suitable substance, and the Solution (a) be either strengthened or diluted, so that 1000 cubic centimetres shall contain exactly 12.59 grammes of iodine; or (b) have its actual strength noted, so that calculations may be made accordingly when the Solution is used." *Br.*

Volumetric Solution of Potassium Bichromate.—(Potassium Bichromate, $K_2Cr_2O_7 = 292.3$.) "Potassium Bichromate, 4.87 grammes; Distilled Water, a sufficient quantity. Put the Potassium Bichromate into the one-litre flask; dissolve it in about half a litre of Distilled Water; dilute the solution with Distilled Water until it has the exact bulk of 1000 cubic centimetres. 100 cubic centimetres of this solution yield 0.0794 gramme of oxygen, and are therefore capable of converting 0.556 gramme of iron from the ferrous to the ferric state. The strength of this Solution should be verified by the aid of pure ferrous ammonium sulphate, or other trustworthy substance, and the Solution (a) be either strengthened or diluted, so that 1000 cubic centimetres shall contain exactly 4.87 grammes of potassium bichromate; or (b) have its actual strength noted, so that calculations may be made accordingly when the Solution is used." *Br.*

Volumetric Solution of Silver Nitrate.—(Silver Nitrate, $AgNO_3 = 168.69$.) "Silver Nitrate, 16.869 grammes; Distilled Water, a sufficient quantity. Put the Silver Nitrate into the one-litre flask;

dissolve it in about half a litre of Distilled Water; dilute the solution with Distilled Water until it has the exact bulk of 1000 cubic centimetres. The Solution should be kept in an opaque stoppered bottle. The strength of this Solution should be verified by the aid of pure sodium chloride or solution of pure hydrochloric acid of known strength, and the Solution (a) be either strengthened or diluted, so that 1000 cubic centimetres shall contain exactly 16.869 grammes of silver nitrate; or (b) have its actual strength noted, so that calculations may be made accordingly when the Solution is used." *Br.*

Volumetric Solution of Sodium Hydroxide.—(Sodium Hydroxide, $\text{NaOH} = 39.76$.) "Purified Sodium Hydroxide, 42 grammes; Distilled Water, a sufficient quantity. Dissolve the Purified Sodium Hydroxide in 1000 cubic centimetres of Distilled Water. Fill a burette with the solution of sodium hydroxide, and cautiously drop this into 100 cubic centimetres of the volumetric solution of sulphuric acid until the acid is exactly neutralized as indicated by litmus. Note the number of cubic centimetres (n) of the solution of sodium hydroxide used, and having then introduced 800 cubic centimetres of it into a graduated jar, augment this quantity by the addition of water, until it becomes $800 \times 100 \div n$ cubic centimetres. 1000 cubic centimetres then contain exactly 39.76 grammes of sodium hydroxide. A decinormal volumetric solution of sodium hydroxide may be prepared by adding, to 100 cubic centimetres of the above volumetric solution, sufficient Distilled Water to produce 1000 cubic centimetres. Alcoholic solutions, normal and decinormal.—Alcohol (90 per cent.) may, when necessary, be used as the solvent. An equivalent proportion of potassium hydroxide, $\text{KOH} = 55.71$, may in certain cases be employed in the place of sodium hydroxide." *Br.*

Volumetric Solution of Sodium Thiosulphate.—(Sodium Thiosulphate, crystallized, $\text{Na}_2\text{S}_2\text{O}_3 \cdot 5\text{H}_2\text{O} = 246.44$.) "Sodium Thiosulphate, in crystals, 28 grammes; Distilled Water, a sufficient quantity. Dissolve the Sodium Thiosulphate in 1000 cubic centimetres of Distilled Water. Fill a burette with this solution, and drop it cautiously into 100 cubic centimetres of the volumetric solution of iodine, until only a faint brown or yellow color remains. Add mucilage of starch and continue the addition of the thiosulphate solution until the blue color is discharged. Note the number of cubic centimetres (n) required to produce this effect; then put 800 cubic centimetres of the same solution into a graduated jar, and augment this quantity by the addition of Distilled Water until it amounts to $800 \times 100 \div n$ cubic centimetres. 1000 cubic centimetres then contain exactly 24.644 grammes of sodium thiosulphate." *Br.*

Volumetric Solution of Sulphuric Acid.—(Sulphuric Acid, $\text{H}_2\text{SO}_4 = 97.34$.) "Sulphuric Acid, 50 grammes; Distilled Water, a sufficient quantity. Dilute the Sulphuric Acid with 900 cubic centimetres of Distilled Water; cool. Prepare a small quantity of sodium carbonate by heating pure sodium bicarbonate to redness in a platinum crucible for a quarter of an hour. Make a solution of 1.053 grammes of the sodium carbonate, and add to it from a burette the solution of sulphuric acid until exact neutrality is obtained, taking care to boil off the carbonic anhydride. Note the number of cubic centimetres used (n); then put 900 cubic centimetres of the solution of sulphuric acid into a graduated jar, and augment this quantity by the addition of Distilled Water until it amounts to $900 \times 20 \div n$ cubic centimetres. 1000 cubic centimetres then contain exactly 48.67 grammes of sulphuric acid. A decinormal volumetric solution of sulphuric acid may be prepared by adding, to 100 cubic centimetres of the above volumetric solution, sufficient Distilled Water to produce 1000 cubic centimetres." *Br.*

INDICATORS OF THE TERMINATION OF REACTIONS IN VOLUMETRIC ESTIMATIONS.

Mucilage of Starch.—"It gives an intensely blue color with iodine, at ordinary temperatures." *Br.*

Solution of Litmus.—"It gives a red color with acids and a blue color with alkalis. It is not distinctly reddened by boric acid. It is reddened by moist carbonic anhydride; hence, when estimating a carbonate with a volumetric solution of an acid, the termination of the reaction is indicated by the neutral tint of the litmus after the liquid under examination has been well boiled." *Br.*

Solution of Methyl Orange.—"It gives a pink color with mineral acids and a faint yellow color with alkalis. It is a trustworthy indicator of excess of ammonia. It is not reddened by moist carbonic anhydride or boric acid." *Br.*

Solution of Neutral Potassium Chromate.—"It gives a red precipitate with silver nitrate, but not while any soluble chloride, bromide, or iodide is present." *Br.*

Solution of Phenol-Phthalein.—"It gives a red color with alkalis, which is discharged by acids. It is the most trustworthy indicator of excess of organic acids. It does not accurately indicate the point of neutralization of ammonia with an acid. For the latter, Tincture of Cochineal is an appropriate indicator." *Br.*

Solution of Potassium Ferricyanide.—"It gives an intensely blue precipitate or coloration with ferrous salts, but none with ferric salts." *Br.*

ART OF PRESCRIBING MEDICINES.

The art of prescribing medicines, *i.e.*, of adapting them to the treatment of individual cases, is one of prime importance, which, however, can scarcely with propriety be fully discussed in a work like the present. As explanatory of our own text, and as affording some guidance to the young practitioner, and also, to the apothecary in interpreting prescriptions, we offer a few remarks, with practical examples.

1. Dose of Medicines.—In this work a minimum and a maximum dose for adults are usually given for each article. In interpreting these doses the practitioner should remember that it is rarely proper to begin with the amount stated as maximum, whilst, on the other hand, the minimum dose will only in exceptional cases produce the full physiological effect of the remedy. When a powerful remedy is being used, and a decided effect is desired, it is best to commence with the smaller dose and to increase cautiously. There are various circumstances modifying the dose which demand attention.

AGE.—The young require a smaller dose than those of maturity; and the old, though their systems are, perhaps, less susceptible to the action of medicines than those of the middle-aged, cannot bear an equally forcible impression from depressing remedies.

The following rule of Young is almost universally adopted.

"For children under twelve years, the doses of most medicines must be diminished in the proportion of the age to the age increased by twelve; thus, at two years to $\frac{1}{6}$; viz., $\frac{2}{2+12} = \frac{1}{6}$. At twenty-one the full dose may be given."

To the above rule some exceptions are offered in particular medicines. Thus, purgatives, diaphoretics, and diuretics must usually be given to children in larger, and narcotics in smaller, doses than those called for by Young's rule. A babe six months old will often not be affected by one-fourth the adult dose of castor oil, or one-sixth the dose of calomel, but will not bear well more than one twenty-fifth the dose of opium.

SEX, TEMPERAMENT, AND IDIOSYNCRASY.—Females usually require somewhat smaller doses than males, and persons of sanguine temperament than the phlegmatic. Constitutional peculiarities, called idiosyncrasies, often exist in individuals, rendering them more than usually susceptible or unsusceptible to the action of certain remedies, the dose of which must be modified accordingly. Thus, in some persons a grain or two of calomel will excite salivation, while in others scarcely any quantity which can be safely administered will produce this effect. Sometimes, moreover, a medicine operates on an individual in a manner wholly different from its ordinary mode. In all such cases experience is the only sure guide, and when a physician is called to a patient, not before known, careful inquiries should always be made.

HABIT.—Generally speaking, the susceptibility to the action of medicines is diminished by their frequent and continued use, and, in order to maintain a given impression, the quantity must be regularly increased. This is especially true in regard to the narcotics, which are sometimes borne in enormous doses by those habituated to their use. It is a good practical rule in prescribing, when circumstances demand the continuance, for a considerable length of time, of some particular effect, to vary the medicine, and employ successively several with the same general powers, so as not too rapidly to exhaust the susceptibility to the action of any individual remedy. A patient accustomed to one narcotic is usually found blunted towards other cognate medicines.

2. Mode of administering Medicines.—This has reference both to the combination of medicines with one another, and to the form in which they are exhibited.

Simplicity in prescription is always desirable. Remedies should never be mixed together without a definite purpose. Those exceedingly complex prescriptions, formerly so much in vogue, of which the ingredients were so numerous as to render altogether impossible a reasonable estimate of their bearing on each other, or of their effects on disease, have been generally abandoned by modern practitioners. The only ground upon which any of them can be justifiably retained is that, by very frequent trials, through a long course of years, and in various states of disease, their influence on the system may have been fully ascertained, so that they may be considered rather in the light of a single remedy than a compound of many. A brief enunciation of a few general principles in regard to the art of combination may be useful.

Remedies of the same general character may be given in connection, in order to increase their energy, or to render their action more certain. It has been well ascertained that substances thus combined will often act vigorously, when, severally, they would produce comparatively little effect, and it sometimes happens that, while their activity is augmented, they are rendered less irritating, as in the case of the drastic cathartics.

Different medicines are very often mixed together, in order to meet different and coexisting indications, without any reference to the influence which they may reciprocally exert on each other. Thus, in the same patient we not unfrequently meet with debility of stomach and constipation of the bowels, connected with derangement of the hepatic function. To answer the indications presented by these morbid conditions, we may properly combine, in the same dose, a tonic, cathartic, and mercurial alternative. For similar reasons we often unite tonics, purgatives, and emmenagogues, anodynes and diaphoretics, emetics and cathartics, antacids, astringents, and tonics.

Medicines acting differently in certain respects are combined to modify each other's powers, or to gain strength at some especial point where their actions overlap. In this way seemingly new powers are sometimes developed, and those previously existing are greatly increased. Examples of such a result are afforded in the official powder of ipecacuanha and opium, which acts as a diaphoretic beyond the capabilities of either of its constituents. The effects of one medicine are, in numerous instances, increased by the influence of another in augmenting the natural susceptibility of the system to its action. Thus, bitters enable cathartics to operate in smaller doses; purgatives awaken the dormant susceptibility to the action of mercury. In some instances, the action of one medicine is promoted by that of another apparently of a nature wholly opposite. Thus, when calomel and opium are given in colic, the purgative operation of the former is facilitated by the relaxation of intestinal spasm produced by the latter. Medicines in addition to the effects for which they are administered, very frequently produce disagreeable symptoms, which may be moderated or altogether prevented by combination with other medicines, and this object may usually be accomplished without in the least degree interfering with the remedial influence desired. Thus, the griping produced by cathartics, and the nausea by these and various other medicines, may be often corrected by the simultaneous use of aromatics. To cover the disagreeable taste or odor of certain medicines, and to afford a convenient vehicle for their administration, are also important objects of combination, as upon these circumstances often depend the acceptability of the medicine to the stomach, and even the possibility of inducing the patient to swallow it. Substances should be preferred as vehicles which are calculated to render the medicine acceptable to the palate and stomach, and in other ways to correct its disagreeable effects; as syrups for powders, the aromatic waters for medicines given in the form of mixture, and carbonic-acid water for the neutral salts.

But, in the mixing of medicines, care should be taken that they are neither chemically nor physiologically incompatible; in other words, that they are not such as will react on each other so as to produce new and unexpected combinations, nor such as will exert contrary and opposite effects upon the system. Thus, when the operation of an acid is desired, an alkali should not be given at the same time, as they unite to form a third substance entirely different from either; nor should a soluble salt of lime, barium, or lead be given with sulphuric acid or a soluble sulphate, as decomposition would ensue, with the production of an inert compound. So, also, in relation to physiological incompatibility, diaphoretics and

diuretics should not, as a general rule, be united with a view to their respective effects, as these are to a certain extent incompatible, one being diminished by whatever has a tendency to increase the other. There are cases, however, in which we may advantageously combine medicines with a view to their chemical reaction, as in the instance of the effervescing draught, and circumstances sometimes call for the union of remedies apparently opposite, as in the case of colic before alluded to, in which opium may be advantageously combined with purgatives. Still, such combinations should never be formed unless with a full understanding of their effects.

The form in which medicines are exhibited is often an object of considerable importance. By variation in this respect, according to the nature of the medicine, the taste of the patient, or the condition of the stomach, we are frequently enabled to secure the favorable operation of remedies, which, without such attention, might prove useless or injurious. Medicines may be given in the solid state, as in the form of powder, pill, troche, or electuary; in the state of mixture, in which a solid is suspended in a liquid, or one liquid is mechanically mixed with another in which it is insoluble; or in the state of solution, under which may be included the various forms of infusion, decoction, tincture, fluidextract, wine, vinegar, syrup, honey, and oxymel.

In writing extemporaneous prescriptions, neatness, order, and precision should always be observed; as independently of the pleasing moral effect, a positive practical advantage results in the greater accuracy which the habit of attending to them gives to the prescriber, and the comparative certainty which they afford that his directions will be strictly complied with. As a general rule, when medicines are combined in prescription, the most important should come first in order, next the adjuvant or corrigent, and lastly the vehicle. Sometimes, however, it is important to indicate to the pharmacist the succession in which the substances should be combined, and this may render convenient a deviation from the order above mentioned. The physician should always be careful either to write out the full name of the medicine, or to employ such abbreviations as cannot be misunderstood. Fatal mistakes have been occasioned by a neglect of this precaution. The following table and formulas explain and illustrate the signs, abbreviations, and methods habitually used in prescribing.

Table of Signs and Abbreviations.

R	Recipe.	Take.	Collyr.	Collyrium.	An eye-water.
āā	Ana.	Of each.	Cong.	Congius vel congii.	A gallon or gallons.
lb	Libra vel libræ.	A pound or pounds.	Decoct.	Decoctum.	A decoction.
ʒ	Uncia vel uncie.	An ounce or ounces.	Ft.	Fiat.	Make.
ʒ	Drachma vel drachmæ.	A drachm or drachms.	Garg.	Gargarysma.	A gargle.
ʒ	Scrupulus vel scrupuli.	A scruple or scruples.	Gm.	Gramme or gram.	15.5 grains.
ʒ	Octarius vel octarii.	A pint or pints.	Gr.	Granum vel grana.	A grain or grains.
fʒ	Fluiduncia vel fluiduncie.	A fluidounce or fluidounces.	Gtt.	Gutta vel guttæ.	A drop or drops.
fʒ	Fluidrachma vel fluidrachmæ.	A fluidrachm or fluidrachms.	Haust.	Haustus.	A draught.
m	Minimum vel minima.	A minim or minims.	Infus.	Infusum.	An infusion.
Cc.	Cubic centimeter.	About 16 minims.	M.	Misce.	Mix.
Chart.	Chartula vel chartulæ.	A small paper or papers.	Mass.	Massa.	A mass.
Coch.	Cochlear vel cochlearia.	A spoonful or spoonfuls.	Mist.	Mistura.	A mixture.
			Pil.	Pilula vel pilulæ.	A pill or pills.
			Pulv.	Pulvis vel pulveres.	A powder or powders.
			Q. S.	Quantum sufficit.	A sufficient quantity.
			S.	Signa.	Write.
			Ss.	Semis.	A half.

Examples of Common Extemporaneous Prescriptions.

Powders.

R Zinci Sulphatis
Pulveris Ipecacuanhæ, āā, gr. xx.
Fiat pulvis.
S. To be taken in a wineglassful of sweetened water.

An active emetic to be used in narcotic and other forms of poisoning.

R Pulveris Jalapæ gr. x.
Potassii Bitartratis ʒii.
Misce.
S. To be taken in syrup or molasses.
A hydragogue cathartic, used in dropsy, in scrofulous inflammation of the joints and when it is necessary to induce watery stools.

R Sulphuris ʒi.
Potassii Bitartratis ʒii.
Misce.
S. To be taken in syrup or molasses.
A laxative used for hemorrhoids and cutaneous diseases.

R Pulveris Rhei gr. x.
Magnesiæ ʒss.
Fiat pulvis.
S. To be taken in syrup or molasses.
A laxative and antacid, used in diarrhœa, dyspepsia, etc.

R Potassii Nitratris ʒi.
Antimonii et Potassii Tartratis gr. i.
Hydrargyri Chloridi Mitis gr. vi.
Fiat pulvis, in chartulas sex dividendus.
S. One to be taken every two hours in syrup or molasses.

A refrigerant, diaphoretic, and alterative, used in bilious fevers; usually called *nitrous powders*.

R Pulveris Calumbæ
Pulveris Zingiberis āā, ʒi.
Fiat pulvis, in chartulas sex dividendus.
S. One to be taken three times a day in syrup or molasses.

A tonic, used in dyspepsia.

Pills.

- R Pulveris Aloes
Pulveris Rhei āā , ʒss .
Olei Caryophylli gtt. x.
Saponis gr. xx.
Misce, et cum aquā fiat massa in pilulas viginti dividenda.
S. Two or three to be taken daily, at bedtime or before a meal.
An excellent laxative in habitual constipation.
- R Pulveris Aloes
Extracti Quassiae āā , ʒi .
Olei Anisi mxx .
Syrupi q. s.
Misce, et fiat massa in pilulas triginta dividenda.
S. Two to be taken once, twice, or three times a day.
A laxative, tonic, and carminative, useful in dyspepsia.

- R Pulveris Scillae gr. xx.
Hydrargyri Chloridi Mitis gr. x.
Pulveris Acaciae,
Syrupi āā , q. s.
Misce, et fiat massa in pilulas decem dividenda.
S. One to be taken twice or three times a day.
A diuretic and alterative, much used in dropsy, especially when complicated with organic visceral disease.
- R Plumbi Acetatis gr. xii.
Pulveris Opii gr. i.
Pulveris Acaciae
Syrupi, āā , q. s. ut fiat massa in pilulas sex dividenda.
S. One every two, three, or four hours.
An astringent much employed in hæmoptysis and uterine hemorrhage.

Mixtures.

- R Magnesiae ʒi .
Syrupi fʒi .
Tere simul, et affunde
Aquae Acidi Carbonici fʒiv .
Fiat haustus.
S. To be taken at a draught, the mixture being well shaken.
An agreeable magnesia mixture.
- R Mannae ʒi .
Fœniculi contusi ʒi .
Aquae bullientis fʒiv .
Fiat infusum et cola; dein adjice.
Magnesii Carbonatis ʒii .
Ft. mist.
S. One-third to be taken every three or four hours till it operates.
- R Olei Ricini fʒiss .
Tincturæ Opii mxxx .
Pulveris Acaciae
Sacchari āā , ʒii .
Aquæ Menthæ Viridis fʒiv .
Acaciam et saccharum cum paululo aquæ menthæ tere; dein oleum adjice, et iterum tere; denique aquam reliquam paulatim infunde, et omnia misce.
S. A tablespoonful to be taken every hour or two hours till it operates.
Used as a gentle laxative in dysentery and diarrhoea. It is usually known by the name of *oleaginous mixture*.

- R Magnesii Sulphatis ʒi .
Syrupi Limonis fʒi .
Aquæ Acidi Carbonici fʒvi .
Misce.
S. To be taken at a draught.
An agreeable mode of administering magnesium sulphate.

Solutions.

- R Quininæ Sulphatis gr. xii.
Acidi Sulphurici Aromatici gtt. xxiv.
Syrupi fʒss .
Aquæ Menthæ Piperitæ fʒi .
Misce.
S. A teaspoonful to be taken every hour or two hours.
A good mode of administering sulphate of quinine in solution.

Infusions.

- R Sennæ ʒiii .
Magnesii Sulphatis
Mannæ āā , ʒss .
Fœniculi ʒi .
Aquæ bullientis Oss.
Macerā per horam in vase leviter clauso, et cola.
S. A teacupful to be taken every four or five hours till it operates.
An excellent purgative in febrile complaints.

- R Calumbæ contusæ
Zingiberis contusi āā , ʒss .
Sennæ ʒii .
Aquæ bullientis Oi.
Macerā per horam in vase leviter clauso, et cola.
S. A wineglassful to be taken morning, noon, and night, or less frequently if it operates too much.
An excellent remedy in dyspepsia with constipation and flatulence.

METRIC PRESCRIPTIONS.

Of late years, since the more general use of the metric system, prescriptions written according to this method have been frequently employed, especially in sections of our country inhabited by those who are accustomed to use the system, which is now almost exclusively employed in Europe. For an explanation of its principles the reader is referred to the article on weights and measures, page 1745. Two distinct methods are in vogue in the United States, called respectively *gravimetric* and *volumetric*; in the *gravimetric* plan, which is almost exclusively used abroad, no measures of capacity are employed, weights being alone used, the unit of weight, the *gramme*, and its subdivisions constituting the sole weights. This method is objected to by many, who are habituated to the usual American practice of measuring instead of weighing liquids, and the *volumetric* method, in which liquids are measured, is preferred, the unit of measure selected being the *cubic centimeter* (abbreviated Cc., and sometimes called *fluigramme*), which is equivalent to a gramme of water at 4° C. One of the principal arguments in favor of the *volumetric* method is that no plan has yet been devised by which the patient can take the dose by weight; teaspoons, tablespoons, or graduated glasses are used altogether for administering liquid medicines, and it would be an almost impracticable task for the practitioner to bear constantly in mind the difference in specific gravity between chloroform, ether, glycerin, syrups, water, and other liquids, yet this would be absolutely necessary in order to secure accurate dosage if the *gravimetric* method were adopted; and in addition the pharmacist would be compelled to weigh the liquids in compounding prescriptions, a troublesome innovation, or to calculate the corresponding volume of each liquid if graduated measures were used. Arabic numerals are exclusively employed in metric formulæ, arranged in a column opposite the names of the ingredients of the prescription; this custom should never be deviated from, as it is one of the means of recognizing metric prescriptions. The following examples will illustrate the various forms of metric prescriptions in general use, but it is very important that but one of these forms should be adopted and *adhered to* if the merits of the system are to be fully realized. We decidedly prefer form Number 1.

Form Number 1.

	Gramma.
℞ Pulv. Aloes	2
Pulv. Rhei	1.5
Olei Caryophylli	.6
Saponis	1.25
Make twenty pills.	

The advantages of the decimal line are that the decimal dot is abolished with its dangerous complications, for a spot or a fly-speck on the prescription paper may increase or decrease the quantity of an ingredient *ten times*, and the use of the decimal line is familiar to all who use a dollar and cents column.

PILLS.

Form Number 2.

℞ Pulv. Aloes	2.
Pulv. Rhei	1.5
Olei Caryophylli	.6
Saponis	1.25
Make twenty pills.	

This form is used frequently, because of the familiarity with the arithmetical method of using a dot to denote a decimal fraction, and where metric prescriptions are altogether in use, as in Continental Europe, there is no necessity for indicating the denomination, gramme being always understood.

Form Number 3.

℞ Pulv. Aloes	2	Gm.
Pulv. Rhei	1.5	Gm.
Olei Caryophylli	.6	Gm.
Saponis	1.25	Gm.
Make twenty pills.		

This form is an improvement on Number 2, and would be far superior to it for use in this country, where prescriptions written in the old system will long continue to be used; for next to writing out in full the word *gramme*, the indication of the unusual quantity by underscoring will prevent its being mistaken for *grain*.

Form Number 1.

(Volumetric.)

	Gm.	Cc.
℞ Magnesie Sulph.	30	
Acid. Sulph. Dil.		6
Syrup. Limonis	30	
Aque	180	
Make a draught.		

LIQUIDS.

Form Number 2.

(Gravimetric.)

℞ Magnesie Sulph.	30.
Acid. Sulph. Dil.	.6
Syrup. Limonis	30.
Aque	180.
Make a draught.	

Form Number 3.

(Volumetric.)

℞ Magnesie Sulph.	30	Gm.
Acid. Sulph. Dil.	.6	Cc.
Syrup. Limonis	30	Cc.
Aque	180	Cc.
Make a draught.		

TABLES OF WEIGHTS AND MEASURES.

APOTHECARIES' WEIGHT. U. S.

Pound.	Troyounces.	Drachms.	Scruples.	Troy Grains.
lb 1 =	12 =	96 =	288 =	5760
	3 1 =	8 =	24 =	480
		3 1 =	3 =	60
			9 1 =	gr. 20

The Imperial Standard Troy weight, at present recognized by the British laws, corresponds with the Apothecaries' weight in pounds, ounces, and grains; but differs from it in the division of the ounce, which, according to the former scale, contains twenty pennyweights, each weighing twenty-four grains.

AVOIRDUPOIS WEIGHT. Br.

Pound.	Ounces.	Drachms.	Troy Grains.

1 minim	=	=	= .91	= 0.00361

¹ The weight of a fluidounce of water at 25° C. (77° F.) according to the Table of Weight and Volume Relations in the U. S. Pharmacopœia 8th Rev. is 454.6 grains.

In converting the weights of liquids heavier or lighter than water into measures, or conversely, a correction must be made for specific gravity. In converting weights into measures, the calculator may proceed as if the liquid was water, and the obtained measure will be to the true measure *inversely* as the specific gravity. In the converse operation, of turning measures into weights, the same assumption may be made, and the obtained weight will be to the true weight *directly* as the specific gravity.

METRIC WEIGHTS AND MEASURES.

The French *metric* system is based upon the idea of employing, as the unit of all measures, whether of length, capacity, or weight, a uniform unchangeable standard, adopted from nature, the multiples and subdivisions of which should follow in decimal progression. To obtain such a standard, the length of one-fourth part of the terrestrial meridian, extending from the equator to the pole, was ascertained. The ten-millionth part of this arc was chosen as the unit of measures of length, and was denominated *meter*.¹ The cube of the tenth part of the meter was taken as the unit of measures of capacity, and denominated *liter*. The weight of distilled water, at its greatest density, which this cube is capable of containing, was called *kilogramme*, of which the thousandth part was adopted as the unit of weight, under the name of *gramme*. The multiples of these measures, proceeding in the decimal progression, are distinguished by employing the prefixes *deca*,² *hecto*, *kilo*, and *myria*, taken from the Greek numerals, and the subdivisions, following the same order, by *deci*, *centi*, *milli*, from the Latin numerals. Since the introduction of this system it has been adopted by the principal nations of Europe, excepting Great Britain, and in many of these its use is compulsory. It is in general use in France, Germany, Austria-Hungary, Italy, Spain, Norway, Sweden, Netherlands, Switzerland, Greece, British India, and South America. It was legalized in Great Britain in 1864, and in the United States by an act of Congress in 1866.

The meter, or unit of length,	=	39.3700 inches.	
The liter, or unit of capacity,	=	33.813819776 fluidounces.	U. S.
The gramme, or unit of weight,	=	15.43235639 Troy grains.	

Upon this basis the following tables have been constructed :

Measures of Length.

		English Inches.					
Millimeter (mm.)	=	.03937					
Centimeter (cm.)	=	.39370					
Decimeter (dm.)	=	3.93700					
Meter (M.)	=	39.37000	Miles.	Rods.	Yards.	Feet.	Inches.
Decameter (Dm.)	=	393.70000	0	0	1	0	3.370
Hectometer (Hm.)	=	3937.00000	0	0	10	2	9.700
Kilometer (Km.)	=	39370.00000	0	0	109	1	1.000
Myriameter (Mm.)	=	393700.00000	0	198	4	1	10.000
			6	56	2	0	4.000

Measures of Capacity.

		English Cubic Inches.		Apothecaries' Measure.	
Milliliter (cc.)	=	.0610233778	=	16.2306	minims.
Centiliter (cl.)	=	.6102337780	=	2.7051	fluidrachms.
Deciliter (dl.)	=	6.1023377800	=	3.3816	fluidounces.
Liter (L.)	=	61.0233778000	=	2.1133	pints.
Decaliter (Dl.)	=	610.2337780000	=	2.6417	gallons.
Hectoliter (Hl.)	=	6102.3377800000			
Kiloliter (Kl.)	=	61023.3778000000			
Myrialiter (Ml.)	=	610233.7780000000			

Measures of Weight.

		Troy Grains.			
Milligramme (mg.)	=	.0154			
Centigramme (cg.)	=	.1543			
Decigramme (dg.)	=	1.5432			
Gramme (Gm.)	=	15.4323			
Decagramme (Dg.)	=	154.3235	lb (Troy).	3	Gr.
Hectogramme (Hg.)	=	1543.2353	0	0	2
Kilogramme (Kg.)	=	15432.3563	0	3	1
Myriagramme (Mg.)	=	154323.5639	2	8	1
			26	9	4
					3.5

¹There are two methods of spelling the metric units in common use, one, the original, *metre*, *litre*, *gramme*; in the other, these are spelled *meter*, *liter*, and *gram*. The U. S. Pharmacopœia (8th Rev.) sanctions both methods, which, in our opinion, is unfortunate. *Mètre* and *litre* are spelled *meter* and *liter*, while the original orthography is retained for *gramme*.

²Deca and hecto are sometimes written *deka* and *hekto*.

RELATIVE VALUE OF WEIGHTS AND MEASURES.

Value of Avoirdupois Weights and Imperial Measures, in Metrical Weights and Measures, as stated in the British Pharmacopœia.

APPROXIMATE MEASUREMENT.

For the sake of convenience, in the absence of proper instruments, we often make use of means of measurement which, though not precise nor uniform, afford results sufficiently accurate for ordinary purposes. Of this kind are certain household implements, of a capacity approaching to uniformity, and corresponding to a certain extent with the regular standard measures. Custom has attached a fixed value to these implements, with which it is proper that the practitioner should be familiar, although their capacity, as they are now made, with the exception of the wineglass, generally somewhat exceeds that at which they were originally and still continue to be estimated. According to the U. S. P. (8th Rev.):

A *tea-cup* is estimated to contain about four fluidounces, or 120 Cc.
 A *wineglass* two fluidounces, or 60 Cc.
 A *tablespoon* (cochlear magnum) . . . half a fluidounce, or 16 Cc.
 A *dessertspoon* (cochlear medium) . . . two fluidrachms, or 8 Cc.
 A *teaspoon* (cochlear parvum) a fluidrachm, or 4 Cc.
 The U. S. D. (19th ed.) prefers to make the equivalents used in this book closer, and have therefore adopted for the tablespoonful 15 Cc., dessertspoonful 7.5 Cc., and teaspoonful 3.75 Cc.

Small quantities of liquid medicines are often administered by *drops*, each of which is usually considered equivalent to a minim, or the sixtieth part of a fluidrachm. The drop of water and of aqueous fluids is, sometimes, about that size; but the same is by no means the case with all medicinal liquids, and the drop even of the same liquid varies much in bulk, according to the circumstances under which it is formed. This is, therefore, an uncertain mode of estimating the quantity of liquids, and should be superseded where minim measures can be had. Certain rules, however, influence the formation of drops, which will enable us to form some notion of their probable relative number, in the same amount of liquid when possessed of the requisite data. Thus, the heavier the liquid, the smaller, other things being equal, is the size of the drops, and the greater their number in a given measure. The drop of chloroform, for example, which is a very heavy liquid, is very small, much smaller than that of alcohol or ether. The greater or less viscosity and greater or less mobility of the liquid have much influence, the former in increasing, the latter in diminishing the size of the drops. The adhesiveness of liquids, which opposes their disposition to leave the surface from which they fall, requires a greater mass to overcome it, and consequently augments the size of the drop. The rapidity of the movement acts in a contrary direction, and the drop from a full bottle should be less than from one more or less emptied. The broader the surface from which they fall, the greater is their size. The drops from a thick-lipped bottle are larger than from one with thin lips.

The results stated in the table on page 1749 were obtained by Stephen L. Talbot. They may be relied on as accurate, and in most cases correspond with the results obtained by Durand and Procter (see *A. J. P.*, i. 169; 1865, p. 389; 1880, p. 337), but should be considered as indicating only the relative number of drops afforded by the several liquids mentioned; for, under other circumstances than those of Talbot's experiments, entirely different results might be obtained as relates to each liquid. The preparations experimented with were those of the U. S. Pharmacopœia of 1870, but the table has been revised to correspond with the preparations of the U. S. P. (8th Rev.)

FRENCH MEASURES.

In reading French medical works, if unacquainted with their customary expressions of measure, we are often left in great uncertainty as to the precise quantity indicated by the names. The following table, translated from the French Codex, will obviate this difficulty. (See Metric Table, page 1745.)

	Grammes.
A coffeespoon (<i>cuillerée à café</i> , Fr., <i>teaspoon</i>) (Fr. Cod. 1895)	5
A dessertspoon (<i>cuillerée à dessert</i> , Fr., <i>dessertspoon</i>), 2 coffeespoons, or	10
A common spoon (<i>cuillerée</i> , Fr., <i>tablespoon</i>), 4 coffeespoons, or	15
A glass (<i>verre</i> , Fr.), 10 common spoons	150
A handful (<i>poignée</i> , Fr.) of barleyseed (Fr. Cod. 1866)	80

TABLES SHOWING SPECIFIC GRAVITY CORRESPONDING WITH DEGREES OF HYDROMETERS.

Baumé's hydrometer is still largely employed. In this instrument the specific gravity of distilled water is assumed as the zero of the descending scale in relation to fluids heavier than itself, and as ten on the ascending scale in relation to lighter fluids. In the following tables the specific gravity of liquids is given corresponding with the several degrees of this hydrometer. The first column of specific gravities is taken from the French Codex. The second column is based on the calculations of Huss. The third column was calculated by Henry Pemberton of Philadelphia, in 1851. The figures in this column correspond with the degrees of the hydrometers formerly prepared by W. H. Pile.

The following formulas, furnished by Pile, may prove useful by enabling any one to calculate the sp. gr. corresponding with the several degrees of Baumé's hydrometer, and, conversely, the degree of Baumé corresponding with the sp. gr.

1. *For Liquids lighter than Water.*—The following formulas give the sp. gr. as represented in the first column in the foregoing table; or, the specific gravity being known, give the corresponding degree of Baumé.

$$\frac{144}{B^{\circ} + 134} = \text{sp. gr.}; \text{ and } \frac{144}{\text{sp. gr.}} - 134 = B^{\circ}.$$

The following formulas apply to the third column of specific gravities.

$$\frac{140}{B^{\circ} + 130} = \text{sp. gr.}; \text{ and } \frac{140}{\text{sp. gr.}} - 130 = B^{\circ}.$$

2. *For Liquids heavier than Water.*—For the first column, $\frac{144}{144 - B^{\circ}} = \text{sp. gr.}$, and $144 - \frac{144}{\text{sp. gr.}} = B^{\circ}$; for the third, $\frac{145}{145 - B^{\circ}} = \text{sp. gr.}$, and $145 - \frac{145}{\text{sp. gr.}} = B^{\circ}$.

FOR LIQUIDS HEAVIER THAN WATER.

Gay-Lussac's centesimal alcoholmeter is applicable only to alcohol. The scale of this instrument is divided into 100 unequal degrees, the zero corresponding to pure water, and 100° to absolute alcohol; and every intermediate degree expresses the percentage of pure alcohol, by measure, contained in the liquors examined. Thus, when the instrument stands at 40° in any alcoholic liquid, it indicates that 100 measures of the liquid contain 40 of pure alcohol and 60 of water. But, as it was graduated for the temperature of 59° of Fahrenheit, the liquors to be tested should be brought to that temperature. *Tralles's centesimal alcoholmeter* is the one used by the U. S. Government in gauging the strength of spirit, and is generally employed in this country by distillers and wholesale dealers in the purchase and sale of alcoholic liquors. The scale of this instrument is, like Gay-Lussac's, divided into 100 unequal parts, each corresponding to the percentage by volume of pure alcohol contained in the liquors examined. As the sp. gr. of water is considered as unity at its temperature of greatest density, 39.8° F., and the degrees of this scale are calculated for 60° F., the zero, corresponding to the density of water, will represent a sp. gr. of .9991.

The table of Tralles on page 1752 gives the percentage of alcohol by measure corresponding with the specific gravity. Under the heading of Alcohol tables (see page 1757), a table of the percentage by weight corresponding with the sp. gr. is given. By means of these tables, in connection with the alcoholmeter, every problem that can arise in reference to the strength of spirituous liquors can be solved; and by the appended table, giving the value of Baumé's degrees in those of Tralles, the facility is still further extended.

Sikes's hydrometer is used in Great Britain in the collection of the excise revenue: it is a brass instrument having a spherical bulb, with a weight at the bottom to make it float upright; the stem is divided into twenty parts, and every other division numbered, from 0 to 10. A series of nine weights are furnished with the instrument, numbered from 10 to 90; these are to be added to the weight at the bottom to cause the hydrometer to sink, so that a reading may be had on the graduated scale; this reading added to the number on the weight employed, gives a figure which indicates the strength of the spirit by referring to a table which accompanies the instrument.

Jones's hydrometer is similar to Sikes's, but by many is regarded as an improvement on it.

RELATIONS BETWEEN THERMOMETERS.

In *Fahrenheit's* thermometer, the freezing point of water is placed at 32°, and the boiling point at 212°, and the number of intervening degrees is 180.

The *Centigrade* or *Celsius's* thermometer, which is now recognized in the U. S. Pharmacopœia and has been adopted generally by scientists, marks the freezing point *zero*, and the boiling point 100°.

In *Réaumur's* thermometer the freezing point is at *zero*, and the boiling point at 80°.

In *De Lisle's* thermometer, used in Russia, the graduation begins at the boiling point, which is marked *zero*, while the freezing point is placed at 150°.

From the above statement, it is evident that 180 degrees of Fahrenheit are equal to 100° of the Centigrade, 80° of Réaumur, and 150° of De Lisle; or 1 degree of the first is equal to $\frac{5}{9}$ of a degree of the second, $\frac{4}{9}$ of a degree of the third, and $\frac{2}{3}$ of a degree of the last. It is easy, therefore, to convert the degrees of one into the equivalent number of degrees of the other; but in ascertaining the corresponding points upon the different scales, it is necessary to take into consideration their different modes of graduation. Thus, as the zero Fahrenheit is 32° below the point at which that of the Centigrade and of Réaumur is placed, this number must be taken into account in the calculation.

1. If any degree on the *Centigrade* scale, either above or below zero, be multiplied by 1.8 the result will, in either case, be the number of degrees above or below 32°, or the freezing point of *Fahrenheit*.

2. The number of degrees between any point of *Fahrenheit's* scale and 32°, if divided by 1.8, will give the corresponding point on the *Centigrade*.

ALCOHOL TABLES.

List of Abbreviations Used in the Following Tables.

abs. = absolute.
alc. = alcohol.
appt. = apparent.
cor. = correction.

dif. = difference.
frac. = fractional.
gal. = gallon.

sp. gr. = specific gravity.
vol. = volume.
wt. = weight.

Alcohol Table (U. S. P. 8th Rev.)

Per cent. vol. alc. ¹	Sp. gr. 15.6° C. ²	Dif. of appt. sp. gr. for 1° C. ³	Frac per cent. ⁴	Vol. in gal. of 100 lbs. av. ⁵	Cor. on fore-going for 0.1 per cent.	No. of gal. official alc. in 100 lbs. av. ⁵	Cor. on fore-going for 0.1 per cent.	Wt. in lbs. av. of 1 gal. U. S. ⁶	Per cent. by wt. abs. alc.	Sp. gr. 15.6° C.	Cor. of sp. gr. for 1° C. ³

¹ Multiply these figures by 1.0585 for the volume per cent. of official alcohol.

² Also approximately the weight in kilograms of one liter of the spirit.

³ Add if the temperature is above, subtract if below, 15.6° C. (60° F.). If the temperature is taken in Fahrenheit degrees, multiply these figures by 0.555.

⁴ Corresponding with a difference in apparent specific gravity of 0.0001.

⁵ For the volume in pints of 100 lbs. of the spirit, multiply these figures by 8; for the volume in fluidounces, multiply by 128; for the volume in liters, multiply by 3.7854.

For the volume of 100 ounces avoirdupois in gallons, divide the figures of the Table by 16; for the volume in pints, divide by 2; for the volume in fluidounces, multiply by 8.

For the volume of 100 grains in fluidounces, multiply by 0.01829; in minims, by 8.777.

⁶ For the weight of one gallon in ounces avoirdupois, multiply these figures by 16; in grains, by 7000; in grammes, by 453.59.

For the weight of one pint in pounds, divide these figures by 8; for the weight of one pint in ounces, multiply by 2; in grains, multiply by 875.

For the weight of one fluidounce in ounces avoirdupois, divide these figures by 8; in grains, multiply by 54.69.

ALCOHOL.

According to E. R. Squibb.

NOTE.—This table was prepared by E. R. Squibb and introduced into the U. S. Pharmacopœia 1890, it is inserted here because it contains data not found in the official alcohol table U. S. P. 8th Rev., see page 1757.

PART I.—From 0 to 10 per cent. of Absolute Alcohol.

Specific Gravity. (Pure water at 15½° C. = 60° F. taken as unity.)		Percentage.			Weight of one gallon, at 15½° C. = 60° F.								Weight of 40 gal- lons to the near- est half pound, at 15½° C. = 60° F.	Weight of one pint, at 15½° C. = 60° F.		
		By weight.	By volume.	Under proof. (Brit. Exclse.)	Of proof spirit. (U. S. Revenue.)	In Grammes.	In Grains.	Avoirdupois Weight.						In Grammes.	In Grain	
								lbs.	ozs.	Grs.	To the nearest ounce.					
At 15½° C. = 60° F.	At 25° C. = 77° F.							lbs.	ozs.	Grs.	lbs.	ozs.	lbs.

Table of Elements and Chemical Substances with their Atomic or Molecular Weights and the Official Table of Multiples.

NAME.	Symbol or Formula.	Atomic or Molecular Weight. H = 1.
Acetal	$C_6H_{14}O_2$	117.22
Acetaldehyde (See Aldehyde, Acetic)		
Acetanilide (Phenylacetamide)	C_8H_9NO	134.09
Acetone	$(CH_3)_2CO$	57.61
Acetophenone (Hypnone)	C_8H_8O	119.16
Acetparaphenetidin (See Acetphenetididn)		
Acetphenetididn (Acetparaphenetidin)	$C_{10}H_{13}NO_2$	177.79
Acid, Acetic	$HC_2H_3O_2$	59.58
" Antimonic	H_3SbO_4	185.82
" Antimonous	H_3SbO_3	169.94
" Arsenic	H_3AsO_4	140.92
" Arsenous (See Arsenic Trioxide)		
" Aurochloric (See Acid, Chlorauric)		
" Benzoic.	$HC_7H_5O_2$	121.13
" Boric	H_3BO_3	61.54
" Camphoric	$H_2C_{10}H_{14}O_4$	198.62
" Carbolic (See Phenol)		
" Carbonic (in solution)	H_2CO_3	61.55
" Chlorauric (Aurochloric)	$HAuCl_4 + 4H_2O$	408.94
" Chlorauric, Anhydrous (Gold Chloride)	$AuCl_3$	301.24
" Chloroplatinic	$H_2PtCl_6 + 6H_2O$	513.66
" Chromic (See Chromium Trioxide)		
" Cinnamic	$HC_8H_7O_2$	146.95
" Citric	$H_3C_6H_5O_7 + H_2O$	208.50
" " Anhydrous	$H_3C_6H_5O_7$	190.62
" Cyanic	$HCNO$	42.72
" Formic	$HCHO_2$	45.67
" Gallic	$HC_7H_5O_5 + H_2O$	186.65
" " Anhydrous	$HC_7H_5O_5$	168.77
" Glycerin-Phosphoric	$H_3C_3H_7O_6P$	170.78
" Hydriodic	HI	126.9
" Hydrobromic	HBr	80.36
" Hydrochloric	HCl	36.18
" Hydrocyanic	HCN	26.84
" Hydrofluoric	HF	19.9
" Hydrosulphuric (See Hydrogen Sulphide)		
" Hypophosphorous	HPH_2O_2	65.53
" Kinic (Quinic)	$HC_7H_{11}O_8$	190.65
" Lactic	$HC_3H_5O_3$	89.37
" Meconic	$C_7H_4O_7$	198.53
" Metaphosphoric	HPO_3	79.41
" Molybdic	H_2MoO_4	160.82
" Nitric	HNO_3	62.57
" Nitrous	HNO_2	46.69
" Oleic.	$HC_{18}H_{33}O_2$	280.14
" Oxalic	$H_2C_2O_4 + 2H_2O$	125.10
" " Anhydrous	$H_2C_2O_4$	89.34
" Palmitic	$HC_{16}H_{31}O_2$	254.32
" Phosphoric	H_3PO_4	97.29

Acid, Phosphorous	H_3PO_3	81.41
" Picric	$\text{HC}_6\text{H}_3(\text{NO}_2)_3\text{O}$	227.41
" Prussic (See Acid, Hydrocyanic)		
" Pyroboric (Tetraboric Acid)	$\text{H}_2\text{B}_4\text{O}_7$	156.76
" Pyrogallic (See Pyrogallol)		
" Pyrophosphoric	$\text{H}_4\text{P}_2\text{O}_7$	176.70
" Salicylic	$\text{HC}_7\text{H}_5\text{O}_3$	137.01
" Silicic	H_2SiO_3	77.84
" Stearic	$\text{HC}_{18}\text{H}_{35}\text{O}_2$	282.14
" Succinic	$\text{H}_2\text{C}_4\text{H}_4\text{O}_4$	117.16
" Sulphanilic	$\text{HC}_6\text{H}_4(\text{NH}_2)\text{SO}_3 + 3\text{H}_2\text{O}$	225.5
" " Anhydrous	$\text{HC}_6\text{H}_4(\text{NH}_2)\text{SO}_3$	171.86
" Sulphuric	H_2SO_4	97.35
" Sulphurous	H_2SO_3	81.47
" Tannic	$\text{HC}_{14}\text{H}_9\text{O}_9$	319.66
" Tartaric	$\text{H}_2\text{C}_4\text{H}_4\text{O}_6$	148.92
" Tetraboric (See Acid, Pyroboric)		
" Titanic (See Titanic Oxide)		
" Trichloroacetic	$\text{HC}_2\text{Cl}_3\text{O}_2$	162.12
" Tungstic (See Tungstic Oxide)		
" Uric	$\text{C}_5\text{H}_4\text{N}_4\text{O}_3$	166.91
" Valeric (Valerianic)	$\text{HC}_6\text{H}_9\text{O}_2$	101.31
Aconitine	$\text{C}_{34}\text{H}_{47}\text{NO}_{11}$	640.55
Agaricin	$\text{C}_{16}\text{H}_{30}\text{O}_5 + \text{H}_2\text{O}$	317.84
Alcohol, Amyl	$\text{C}_5\text{H}_{11}\text{OH}$	87.43
" Benzyl	$\text{C}_7\text{H}_7\text{OH}$	107.25
" Ethyl (Ethyl Hydroxide)	$\text{C}_2\text{H}_5\text{OH}$	45.70
" Methyl	CH_3OH	31.79
Aldehyde, Acetic	$\text{C}_2\text{H}_4\text{O}$	43.70
" Benzoic (See Benzaldehyde)		
" Cinnamic (See Cinnamic Aldehyde)		
" Formic (See Formaldehyde)		
Allyl-iso-thiocyanate	CSNC_3H_5	98.40
Allyl-sulphocarbamide (See Thiosinamine)		
Alum (Aluminum and Potassium Sulphate)	$\text{AlK}(\text{SO}_4)_2 + 12\text{H}_2\text{O}$	471.02
" Anhydrous	$\text{AlK}(\text{SO}_4)_2$	256.46

Specific Gravity Corrections.

Table of Corrections to be applied to apparent specific gravities given by glass apparatus
(pycnometer, hydrometer, Westphal balance having a glass plummet,
etc.) standardized at $\frac{15^{\circ}\text{C.}}{15^{\circ}\text{C.}}$ to obtain sp. gr. $\frac{25^{\circ}\text{C.}}{25^{\circ}\text{C.}}$.

PART III

SECTION II

NATIONAL FORMULARY OF UNOFFICIAL PREPARATIONS

The National Formulary, 3rd edition, is issued by the American Pharmaceutical Association and is here printed in abstract, with the permission of the Council of the Association, the printing of the *full text* of this edition of the Formulary by any publisher except their own being forbidden by a resolution passed by the Association at its annual meeting in Indianapolis in 1906.

The National Formulary is intended to serve as a guide to pharmacists and physicians for preparations which are unofficial and not in the United States Pharmacopœia but which are in use in this country. A bound copy of the 3rd edition should be in the hands of every pharmacist, and can be purchased for a small sum from booksellers, wholesale druggists or from the General Secretary of the American Pharmaceutical Association.

ACETUM AROMATICUM. N. F.

Aromatic Vinegar

The formula of this preparation is identical with that of the 2d ed. N. F. It contains the volatile oils of lavender, rosemary, juniper, peppermint, cinnamon, lemon and cloves, dissolved in alcohol, acetic acid and water.

ACIDUM CARBOLICUM IODATUM. N. F.

Iodized Carbolie Acid

[Phenol Iodatum, Iodized Phenol]

The formula for Iodized Carbolie Acid was not changed in the last revision of the N. F., with the exception that the quantities are expressed in parts by weight instead of grammes. It is made from iodine, phenol and glycerin. It is used externally as a convenient form of applying iodine and phenol when indicated.

ACIDUM CITRICUM SACCHARATUM. N. F.

Saccharated Citric Acid

The formula for this preparation does not differ from that of the 2d ed. N. F. This powder is used by mixing it with an equal weight of saccharated sodium bicarbonate (see page 1812) and adding to water to form an effervescing solution which is refrigerant and laxative.

ACIDUM HYPOPHOSPHOROSUM. N. F.

(U. S. P. = 30 per cent.)

Hypophosphorous Acid

The 3d ed. N. F. introduces a process for making hypophosphorous acid by decomposing potassium hypophosphite with tartaric acid, the liquids used being distilled water and diluted alcohol. The strength is the same as that of the U. S. P. (8th Rev.), 30 per cent. (see page 45). The 2d ed. N. F. preparation was a 10 per cent. acid. It is intended to be used for making diluted hypophosphorous acid.

ACIDUM METAPHOSPHORICUM DILUTUM. N. F.

Diluted Metaphosphoric Acid [Acidum Phosphoricum Glaciale Dilutum, Diluted Glacial Phosphoric Acid]

This diluted acid is intended to be of the same strength as the official diluted phosphoric acid. Inasmuch as glacial phosphoric acid, from which it is made, as found in commerce usually contains sodium phosphate in large quantity as an impurity, a similar formula was abandoned by the U. S. Pharmacopœia because of its uncertain strength, and this diluted acid should not be used in place of the official diluted phosphoric acid. (See page 63.)

ACIDUM TARTARICUM SACCHARATUM.
N. F.

Saccharated Tartaric Acid

The formula for this preparation does not differ from that of the 2d ed. N. F. Used by dissolving in water with an equal weight of saccharated sodium bicarbonate (see page 1812) to form an effervescing mixture which is refrigerant and laxative.

AQUA SEDATIVA. N. F.

Sedative Water

[*Lotio Ammonico-Camphorata (Codex),*
Eau Sedative de Raspail]

The formula for this preparation is the same as that found in the 2d ed. N. F.
Average dose: 8 Cc. (2 fluidrachms).

BALSAMUM TRAUMATICUM. N. F.

Traumatic Balsam

[*Turlington's Balsam, Friar's Balsam*]

The official *Tinctura Benzoini Composita* (see page 1256) is a simplified form of Turlington's Balsam and is preferred to this preparation.
Average dose: 2 Cc. (30 minims).

BISMUTHI OXIDUM HYDRATUM. N. F.

Hydrated Oxide of Bismuth

This form of bismuth is a creamy white powder well adapted for mixing with water to form a *Cream of Bismuth* to be used externally as an application to the skin.

BOROGLYCERINUM. N. F.

Boroglycerin

[*Glyceryl Borate, Boroglyceride*]

This is a solid or semi-solid, intended for use in making a glycerite of boroglycerin by adding to it an equal weight of glycerin and heating with a gentle heat until dissolved. The process in the 2d ed. N. F. was the same as that of the 3d ed. Used as a preservative for animal and vegetable products.

CAFFEINÆ SODIO-BENZOAS. N. F.

Caffeine Sodio-Benzozate

This powder contains 50 per cent. of caffeine with 50 per cent. of sodium benzoate, as in the 2d ed. N. F. It is used as a nerve stimulant.
Average dose: 0.2 Gm. (3 grains).

CAFFEINÆ SODIO-SALICYLAS. N. F.

Caffeine Sodio-Salicylate

This powder contains 50 per cent. of caffeine with sodium salicylate, as in the 2d ed. N. F. It is used in rheumatism.
Average dose: 0.2 Gm. (3 grains).

CAMPHO-MENTHOL. N. F.

Camphor and Menthol

A new preparation in the 3d ed. N. F. Equal parts by weight of camphor and menthol. Applied locally in neuralgia.

CERATUM CAMPHORÆ COMPOSITUM.

N. F.

Compound Camphor Cerate

[*Ceratum Camphoratum, Camphor Ice*]

Largely used at one time as a healing application to chapped skin. It contains camphor, white wax, castor oil, spermaceti, phenol, oil of bitter almond and benzoic acid.

CHLORAL CAMPHORATUM. N. F.

Camphorated Chloral [*Chloral et Camphora,*
Chloral and Camphor]

Equal parts by weight of hydrated chloral and camphor as in the 2d ed. N. F. Used locally to relieve pain.

COLLODIUM IODATUM. N. F.

Iodized Collodion

A five per cent., by weight, solution of iodine in flexible collodion as in the 2d ed. N. F. Used externally as a discutient.

COLLODIUM IODOFORMATUM. N. F.

Iodoform Collodion

A five per cent. by weight solution of iodoform in flexible collodion as in 2d ed. N. F. Used locally.

COLLODIUM SALICYLATUM
COMPOSITUM. N. F.

Compound Salicylated Collodion
[*Corn Collodion*]

The proportions of the ingredients are the same as in the 2d ed. N. F. It contains salicylic acid, extract of Indian hemp, alcohol and flexible collodion. Used in the treatment of corns.

COLLODIUM TIGLII. N. F.

Croton Oil Collodion

A ten per cent. by weight solution of croton oil in flexible collodion as in 2d ed. N. F. Used locally as a counter-irritant.

CORDIALE RUBI FRUCTUS. N. F.

Blackberry Cordial

The proportions of the ingredients are nearly the same as in the 2d ed. N. F. It contains cin-

namon, cloves, nutmeg, fresh blackberry juice, syrup, and diluted alcohol, and is used as a remedy in diarrhoea.

Dose: 8 to 16 Cc. (2 to 4 fluidrachms).

DECOCTUM ALOES COMPOSITUM. N. F.

Compound Decoction of Aloes

The formula for this decoction does not differ from that of the 2d ed. N. F. It contains extract of aloes, myrrh, saffron, potassium carbonate, extract of glycyrrhiza, compound tincture of cardamom and water. It is used as a laxative or purgative in the *dose* of 8 Cc. to 32 Cc. (2 to 8 fluidrachms).

ELIXIR ACIDI SALICYLICI. N. F.

Elixir of Salicylic Acid

The formula for this elixir is the same as that of the 2d ed. N. F. It contains 5 grains of salicylic acid in 1 fluidrachm of finished elixir, and is used in the treatment of rheumatism.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR AMMONII BROMIDI. N. F.

Elixir of Ammonium Bromide

The formula for this elixir was changed in the 3d ed. N. F. by dropping the citric acid which was directed in the 2d ed. N. F. It contains 5 grains of ammonium bromide in 1 fluidrachm of finished elixir, and is used as a nerve sedative.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR AMMONII VALERIANATIS. N. F.

Elixir of Ammonium Valerianate

The title of this elixir should have been changed to Elixir Ammonii Valeratis, to conform to the name of the salt in the U. S. P. 8th Rev., "valerate." The formula for this elixir was changed in the 3d ed. N. F. by increasing the proportion of chloroform about 40 per cent. It contains 2 grains of ammonium valerate in 1 fluidrachm of finished elixir.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR AMMONII VALERIANATIS ET QUININÆ. N. F.

Elixir of Ammonium Valerianate and Quinine

The title should have been changed as in the elixir preceding this, for the reasons there given. It contains $\frac{1}{2}$ of a grain of quinine hydrochloride and 2 grains of ammonium valerate in 1 fluidrachm of finished elixir.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR ANISI. N. F.

Elixir of Anise [Aniseed Cordial]

The formula for this elixir was changed in the 3d ed. N. F. by using purified talc instead

of magnesium carbonate as a clarifying substance. It contains anethol, oil of fennel, spirit of bitter almond, alcohol, syrup and water. Used as a vehicle, also as a carminative for infants.

Average dose: Infants, 1 Cc. (15 minims).

ELIXIR APII GRAVEOLENTIS COMPOSITUM. N. F.

Compound Elixir of Celery

This elixir should always be prescribed under its full name, "Apii Graveolentis," to avoid the possibility of "Apii" being mistaken in handwriting for "Opii." The formula is the same as that of the 2d ed. N. F. It contains fluidextracts of celery seed, coca, kola, viburnum prunifolium, with alcohol and aromatic elixir. Used as a stimulant in nervous affections.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR BISMUTHI. N. F.

Elixir of Bismuth

This formula has been improved in the 3d ed. N. F., bismuth and ammonium citrate being replaced by glycerite of bismuth. Two grains of bismuth and sodium tartrate are contained in 1 fluidrachm of finished elixir.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR BUCHU. N. F.

Elixir of Buchu

In this elixir magnesium carbonate has been replaced in the 3d ed. N. F. by purified talc as a clarifying agent. It contains fluidextract of buchu, alcohol, syrup and aromatic elixir. About $7\frac{1}{2}$ grains of buchu are represented by 1 fluidrachm of finished elixir. It is used as a diuretic.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR BUCHU COMPOSITUM. N. F.

Compound Elixir of Buchu

The comments on Elixir of Buchu apply to this elixir. Compound fluidextract of buchu (page 1794) is used instead of the simple fluidextract. About 15 minims of compound fluidextract of buchu are represented in 1 fluidrachm of finished elixir. It is used as a diuretic.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR BUCHU ET POTASSII ACETATIS. N. F.

Elixir of Buchu and Potassium Acetate

The formula for this elixir is the same as that of the 2d ed. N. F. It contains 5 grains of potassium acetate and the equivalent of $7\frac{1}{2}$ grains of buchu in 1 fluidrachm of finished elixir. It is used as a diuretic.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR CAFFEINÆ. N. F.**Elixir of Caffeine**

The formula for this elixir is nearly the same as that of the 2d ed. N. F. It contains 1 grain of caffeine in 1 fluidrachm of finished elixir. It is used as a nerve stimulant.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR CALCII BROMIDI. N. F.**Elixir of Calcium Bromide**

The formula for this elixir was changed in the 3d ed. N. F., diluted hydrobromic acid being used to aid in dissolving the calcium bromide instead of the citric acid used in the 2d ed. N. F.

It contains 5 grains of calcium bromide in 1 fluidrachm of finished elixir, and is used as a nervine.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR CALCII HYPOPHOSPHITIS. N. F.**Elixir of Calcium Hypophosphite**

The formula for this elixir was changed in the 3d ed. N. F., hypophosphorous acid being used to aid in dissolving the calcium hypophosphite instead of the citric acid used in the 2d ed. N. F.

It contains 2 grains of calcium hypophosphite in 1 fluidrachm of finished elixir. It is used as an alterative.

Average dose: 8 Cc. (2 fluidrachms).

ELIXIR CALCII LACTOPHOSPHATIS. N. F.**Elixir of Calcium Lactophosphate**

No change was made in the formula for this elixir, the ingredients and quantities being the same as those directed in the 2d ed. N. F.

It contains 1 grain of calcium lactate or about $1\frac{1}{2}$ grains of so-called calcium lactophosphate in 1 fluidrachm of finished elixir. It is used as an alterative.

Average dose: 8 Cc. (2 fluidrachms).

ELIXIR CATHARTICUM COMPOSITUM.**N. F.****Compound Cathartic Elixir**

The formula for this elixir was completely revised for the 3d ed. N. F., the fluidextracts of frangula and rhubarb replacing those of podophyllum, leptandra and jalap used in the 2d ed. N. F., while spirit of peppermint, solution of potassium hydroxide, saccharin and aromatic elixir replace potassium and sodium tartrate, sodium bicarbonate, compound elixir of taraxacum, and elixir of glycyrrhiza of the 2d ed. N. F. Fluidextract of senna was used in both formulas.

Average dose: Aperient, 4 Cc. (1 fluidrachm); Cathartic, 12 Cc. (3 fluidrachms).

ELIXIR CHLOROFORMI COMPOSITUM.**N. F.****Compound Elixir of Chloroform**

The formula for this elixir was not changed in the 3d ed. N. F. It is recommended that the name "*Chloroform Paregoric*" formerly used as a synonym for this elixir be abandoned, in order that confusion with official paregoric may be prevented. It is used as an anodyne and carminative.

Average dose: 2 Cc. ($\frac{1}{2}$ fluidrachm).

ELIXIR CINCHONÆ. N. F.

(Elixir of Cinchona from "Alkaloids.")

Elixir of Cinchona Elixir Calisaya**[Compound Elixir of Quinine]**

The formula for this elixir was completely changed in the 3d ed. N. F., the alkaloids of cinchona being employed instead of the tincture of cinchona used in the 2d ed. N. F., or in other words the old compound elixir of quinine is now called elixir of cinchona. This course is to be commended, notwithstanding the unfavorable criticism made by some writers, who insist that it is no longer entitled to the name of elixir of cinchona because it is not made directly from a preparation of the bark; the alkaloids are made *from the bark*, however, and there certainly can be no good reason for compelling the pharmacist to dispense the elixir of the 2d ed. N. F., which has the fault of precipitating continually, and which cannot be mixed with preparations containing salts of iron without producing inky compounds. The introduction of this new elixir of cinchona containing alkaloids in definite quantities makes it unnecessary to retain detannated elixir of cinchona and a separate formula for compound elixir of quinine, both of which were dropped. It is used as a tonic and vehicle for other preparations. This elixir now contains 1 grain of quinine sulphate and $\frac{1}{2}$ grain each of cinchonidine and cinchonine sulphates in 1 fluidounce of finished elixir, and is used as a tonic.

Average dose: 8 Cc. (2 fluidrachms).

ELIXIR CINCHONÆ ET FERRI. N. F.**Elixir of Cinchona and Iron [Elixir of Calisaya and Iron, Ferrated Elixir of Calisaya]**

The formula for this elixir was not changed in strength in the 3d ed. N. F. The color is darker than that of the 2d ed. N. F., due to the use of tincture of cudbear in the elixir of cinchona now used.

It contains 2 grains of soluble ferric phosphate in 1 fluidrachm of finished elixir. It is used as a chalybeate tonic.

Average dose: 8 Cc. (2 fluidrachms).

ELIXIR CINCHONÆ ET HYPOPHOSPHITUM. N. F.

Elixir of Cinchona and Hypophosphites
Elixir of Calisaya and Hypophosphites

The formula for this elixir was changed in the 3d ed. N. F. by replacing the citric acid in the 2d ed. N. F. with hypophosphorous acid. The use of the elixir of cinchona (made now from alkaloids) changes the taste and appearance of this elixir, which contains 1 grain each of calcium and sodium hypophosphites in 1 fluidrachm of finished elixir. It is used as a tonic and alterative.

Average dose: 8 Cc. (2 fluidrachms).

ELIXIR CINCHONÆ, FERRI, BISMUTHI ET STRYCHNINÆ. N. F.

Elixir of Cinchona, Iron, Bismuth and Strychnine [Elixir of Calisaya, Iron, Bismuth and Strychnine]

The strength of this elixir was not changed in the 3d ed. N. F. It contains 1-100th of a grain of strychnine sulphate, 1 grain of bismuth and sodium tartrate and 2 grains of soluble ferric phosphate in 1 fluidrachm of finished elixir, and is used as a bitter tonic and stomachic.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR CINCHONÆ, FERRI ET BISMUTHI. N. F.

Elixir of Cinchona, Iron and Bismuth [Elixir of Calisaya, Iron and Bismuth]

The formula for this elixir was changed in the 3d ed. N. F., glycerite of bismuth replacing bismuth and ammonium citrate of the 2d ed. N. F. It contains 1 grain of bismuth and sodium tartrate, 1½ grains of soluble ferric phosphate, in 1 fluidrachm of finished elixir, and is used as a bitter tonic and stomachic.

Average dose: 8 Cc. (2 fluidrachms).

ELIXIR CINCHONÆ, FERRI, ET CALCI LACTOPHOSPHATIS. N. F.

Elixir of Cinchona, Iron and Calcium Lactophosphate [Elixir of Calisaya, Iron, and Lactophosphate of Lime]

The formula for this elixir is the same as that in the 2d ed. N. F. It contains ½ grain of calcium lactate (equivalent to about ¾ grain of the so-called calcium lactophosphate), nearly 2 grains of soluble ferric phosphate, and is tonic and alterative.

Average dose: 8 Cc. (2 fluidrachms).

ELIXIR CINCHONÆ, FERRI ET PEPSINI. N. F.

Elixir of Cinchona, Iron and Pepsin [Elixir of Calisaya, Iron and Pepsin]

The formula for this elixir was changed in the 3d ed. N. F. by replacing the pepsin and

hydrochloric acid used in the 2d ed. N. F. by glycerite of pepsin. It contains 1 grain of pepsin and about 1½ grains of soluble ferric phosphate in 1 fluidrachm of finished elixir, and is used as a tonic and stomachic.

Average dose: 8 Cc. (2 fluidrachms).

ELIXIR CINCHONÆ, FERRI ET STRYCHNINÆ. N. F.

Elixir of Cinchona, Iron and Strychnine
[Elixir of Calisaya, Iron and Strychnine]

The formula for this elixir was very slightly changed in the 3d ed. N. F., 15 Cc. of water being replaced by 10 Cc. for dissolving the strychnine sulphate. This, of course, does not affect the strength. It contains 1-100th of a grain of strychnine sulphate and 2 grains of soluble ferric phosphate in 1 fluidrachm of finished elixir, and is used as a bitter tonic.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR CINCHONÆ, PEPSINI ET STRYCHNINÆ. N. F.

Elixir of Cinchona, Pepsin and Strychnine
Elixir of Calisaya, Pepsin and Strychnine

The formula for this elixir was improved in the 3d ed. N. F. by the addition of cinchonidine sulphate. It contains 1-100th grain of strychnine sulphate, ½ grain quinine sulphate, 1-16th grain each of cinchonidine and cinchonine sulphates, and 1 grain of pepsin in 1 fluidrachm of finished elixir. It is used as a tonic, stomachic, and digestive.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR COCÆ. N. F.

Elixir of Coca [Elixir of Erythroxyton]

This is a new elixir in the 3d ed. N. F. It is made from fluidextract of coca, tincture of vanilla, alcohol, syrup and aromatic elixir, about 7½ grains of coca leaf being represented in 1 fluidrachm of finished elixir. It is used as a stimulant.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR COCÆ ET GUARANÆ. N. F.

Elixir of Coca and Guarana
[Elixir of Erythroxyton and Guarana]

This is a new elixir in the 3d ed. N. F. It contains fluidextracts of coca and guarana with compound elixir of taraxacum, about 7½ grains each of coca leaf and guarana being represented by 1 fluidrachm of finished elixir. It is used as a stimulant.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR CORYDALIS COMPOSITUM. N. F.
Compound Elixir of Corydalis

The formula for this elixir is the same as that of the 2d ed. N. F. It contains about 3

grains of potassium iodide in 1 fluidrachm of finished elixir, with small quantities of the fluid-extracts of corydalis, stillingia, xanthoxylum and iris.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR CURASSAO. N. F.

Elixir of Curacao [Curacao Cordial]

The only change in the formula for this elixir in the 3d ed. N. F. is the slight increase in the proportion of spirit of curacao. It contains spirit of curacao, a little orris root, citric acid, alcohol, syrup and water. It is used solely as a vehicle.

Average dose: 16 Cc. (4 fluidrachms).

ELIXIR DIGESTIVUM COMPOSITUM. N. F.

Compound Digestive Elixir [Compound Elixir of Pepsin]

The formula for this elixir was slightly changed in the 3d ed. N. F., the quantity of lactic acid and hydrochloric acid being reduced. It contains pepsin, pancreatin, diastase, lactic acid, hydrochloric acid, tincture of cudbear, glycerin, water and aromatic elixir. Pepsin and pancreatin should never be used in the same liquid. Digestive.

Average dose: 8 Cc. (2 fluidrachms).

ELIXIR ERIODICTYI AROMATICUM. N. F.

Aromatic Elixir of Eriodictyon [Aromatic Elixir of Yerba Santa, Elixir Corrigenis]

The formula for this elixir was very slightly changed in the 3d ed. N. F., the quantities of fluidextract of eriodictyon and magnesium carbonate being slightly reduced. It is made from fluidextract of eriodictyon, syrup, powdered pumice, magnesium carbonate and compound elixir of taraxacum. It is used chiefly as a vehicle for disguising the taste of quinine sulphate and other bitter substances.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR EUCALYPTI. N. F.

Elixir of Eucalyptus

The formula for this elixir is nearly the same as that in the 2d ed. N. F. The only change in the 3d ed. N. F. is the replacing of magnesium carbonate by purified talc. It contains about 7½ grains of eucalyptus in 1 fluidrachm of finished elixir, syrup of coffee and compound elixir of taraxacum being employed in the preparation. It is used as a tonic.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR EUONYMI. N. F.

Elixir of Euonymus [Elixir of Wahoo]

The formula for this elixir is the same as that in the 2d ed. N. F. About 9½ grains of euonymus are represented in 1 fluidrachm of the

finished elixir, which contains syrup of coffee and compound elixir of taraxacum. It is used as a diuretic and cholagogue.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR FERRI HYPOPHOSPHITIS. N. F.

Elixir of Hypophosphite of Iron

The English name of this elixir was changed in the 3d ed. N. F. from Elixir of Ferric Hypophosphite to Elixir of Hypophosphite of Iron. No change was made in the proportion of the ingredients, 1 grain of iron hypophosphite being contained in 1 fluidrachm of finished elixir. It is used as an alternative and chalybeate tonic.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR FERRI LACTATIS. N. F.

Elixir of Lactate of Iron

The English name of this elixir was changed in the 3d ed. N. F. from Elixir of Ferrous Lactate to Elixir of Lactate of Iron. The name "Lactate of Iron" also replaces "Ferrous Lactate" used in the 2d ed. N. F. No change was made in the ingredients or quantities. One grain of lactate of iron and 3 grains of potassium citrate are contained in 1 fluidrachm of finished elixir. It is used as a chalybeate tonic.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR FERRI PHOSPHATIS. N. F.

Elixir of Phosphate of Iron

The English name of this elixir was changed in the 3d ed. N. F. from Elixir of Ferric Phosphate to Elixir of Phosphate of Iron, and the word "soluble" has been added to ferric phosphate. Two grains of soluble ferric phosphate are contained in one fluidrachm of the finished elixir. It is used as a chalybeate tonic.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR FERRI PYROPHOSPHATIS. N. F.

Elixir of Pyrophosphate of Iron

The English name of this elixir was changed in the 3d ed. N. F. from Elixir of Ferric Pyrophosphate to Elixir of Pyrophosphate of Iron. No change was made in the ingredients or quantities used in the 2d ed. N. F., except that the word "soluble" has been added to ferric pyrophosphate. It contains 2 grains of soluble ferric pyrophosphate in 1 fluidrachm of finished elixir. It is used as a chalybeate tonic.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR FERRI PYROPHOSPHATIS, QUININÆ ET STRYCHNINÆ. N. F.

Elixir of Pyrophosphate of Iron, Quinine, and Strychnine.

This is a new preparation in the 3d ed. N. F., and differs from the official elixir of iron, qui-

nine and strychnine phosphates in containing soluble ferric pyrophosphate instead of phosphate, while the quinine in the official elixir is replaced by quinine sulphate. It contains 1-128th grain of strychnine, $\frac{1}{2}$ grain of quinine sulphate, and 2 grains of soluble ferric pyrophosphate in 1 fluidrachm of finished elixir. The additional ingredients are citric acid, oil of orange, alcohol, syrup, ammonia water and distilled water. It is used as a chalybeate tonic.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR FERRI, QUININÆ ET STRYCHNINÆ. N. F.

Elixir of Iron, Quinine and Strychnine

This elixir does not differ greatly from that of the 2d ed. N. F. It contains about 1 grain of ferric chloride, $\frac{1}{2}$ grain quinine hydrochloride, and 1-100th grain of strychnine sulphate in 1 fluidrachm of finished elixir. It is used as a chalybeate tonic.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR FRANGULÆ. N. F.

Elixir of Frangula [Elixir of Buckthorn]

The formula for this elixir does not differ from that of the 2d ed. N. F. It is made from fluidextract of frangula, alcohol, compound elixir of taraxacum, and aromatic elixir. It represents about 15 grains of frangula in 1 fluidrachm of the finished elixir. It is used as a laxative.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR GENTIANÆ. N. F.

Elixir of Gentian

The formula for this elixir does not differ from that of the 2d ed. N. F. It is made from fluidextract of gentian, compound spirit of cardamom, solution of ferric sulphate, ammonia water, alcohol, water and aromatic elixir, and represents about 2 grains of gentian in 1 fluidrachm of the finished elixir. It is used as a bitter tonic.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR GENTIANÆ CUM TINCTURA FERRI CHLORIDI. N. F.

Elixir of Gentian with Tincture of Chloride of Iron

The formula for this elixir does not differ from that of the 2d ed. N. F. The English name was changed in the 3d ed. from Elixir of Gentian with Tincture of Ferric Chloride, to Elixir of Gentian with Tincture of Chloride of Iron. It represents $\frac{3}{4}$ of a grain of ferric chloride and nearly 2 grains of gentian in 1 fluidrachm of the finished elixir, and is used as a bitter tonic.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR GENTIANÆ ET FERRI PHOSPHATIS. N. F.

Elixir of Gentian and Phosphate of Iron [Elixir Gentianæ Ferratum, Ferrated Elixir of Gentian, Ferrophosphated Elixir of Gentian]

The English name of this elixir was changed in the 3d ed. N. F. from Elixir of Gentian and Ferric Phosphate to Elixir of Gentian and Phosphate of Iron, but the formula does not differ from that of the 2d ed. N. F., except that the word soluble has been added to ferric phosphate. One grain of soluble ferric phosphate and about 2 grains of gentian are represented in 1 fluidrachm of the finished elixir. It is used as a chalybeate and tonic.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR GENTIANÆ GLYCERINATUM. N. F. Glycerinated Elixir of Gentian

This is a new elixir in the 3d ed. N. F. It is made from the fluidextracts of gentian and taraxacum, acetic ether, phosphoric acid, tincture of sweet orange peel, compound tincture of cardamom, solution of saccharin, glycerin, sugar and white wine. It is a tonic agreeable to the taste and will undoubtedly prove a valuable addition to the list of tonic elixirs. The use of saccharin, however, is questionable, in view of the prejudice against it, and as glycerin and sugar are both sweetening agents, its employment seems unnecessary.

Average dose: 8 Cc. (2 fluidrachms).

ELIXIR GLYCYRRHIZÆ. N. F.

Elixir of Glycyrrhiza [Elixir of Licorice]

The formula for this elixir does not differ from that of the 2d ed. N. F., except in the addition of a small quantity of magnesium carbonate to aid in the filtration. It is made from fluidextract of glycyrrhiza and aromatic elixir. It is used as a vehicle and flavoring agent.

Average dose: 8 Cc. (2 fluidrachms).

ELIXIR GLYCYRRHIZÆ AROMATICUM. N. F.

Aromatic Elixir of Glycyrrhiza Aromatic Elixir of Licorice

The formula for this elixir was changed in the 3d ed. N. F., the quantity of volatile oils having been practically doubled. It contains fluidextract of licorice, oils of cloves, cinnamon, myristica and fennel, with aromatic elixir; purified talc replaces magnesium carbonate. It is used as a vehicle.

Average dose: 8 Cc. (2 fluidrachms).

ELIXIR GLYCEROPHOSPHATUM. N. F.**Elixir of Glycerophosphates**

This is a new elixir in the 3d ed. N. F. It contains 1 grain of absolute sodium glycerophosphate, and $\frac{1}{2}$ grain calcium glycerophosphate, in 1 fluidrachm of finished elixir. The additional ingredients are phosphoric acid, glycerin, aromatic elixir and distilled water. It is used as an alternative.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR GRINDELIAE. N. F.**Elixir of Grindelia**

The formula for this elixir does not differ from that of the 2d ed. N. F. It is made from fluidextract of grindelia, compound spirit of orange, alcohol and compound elixir of taraxacum. About 4 grains of grindelia are represented in 1 fluidrachm of the finished elixir. It is used in the treatment of asthma.

Average dose: 8 Cc. (2 fluidrachms).

ELIXIR GUARANÆ. N. F.**Elixir of Guarana**

The formula for this elixir does not differ from that of the 2d ed. N. F. It is made from fluidextract of guarana, aromatic elixir and compound elixir of taraxacum. About 12 grains of guarana are represented in 1 fluidrachm of finished elixir. It is used as a nervous stimulant.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR HUMULI. N. F.**Elixir of Humulus [Elixir of Hops]**

The formula for this elixir does not differ from that of the 2d ed. N. F., except in the substitution of purified tale for the magnesium carbonate. It is made from fluidextract of hops, purified tale, tincture of vanilla, compound elixir of taraxacum and aromatic elixir. About $7\frac{1}{2}$ grains of hops are represented in 1 fluidrachm of finished elixir. It is used as a mild sedative.

Average dose: 8 Cc. (2 fluidrachms).

ELIXIR HYPOPHOSPHITUM. N. F.**Elixir of Hypophosphites**

The formula for this elixir does not differ from that of the 2d ed. N. F., except in the replacing of the citric acid used in the 2d. ed. by hypophosphorous acid. It is made from calcium, sodium and potassium hypophosphites, hypophosphorous acid, water, glycerin, compound spirit of cardamom and aromatic elixir. It contains 3 grains of calcium hypophosphite and 1 grain each of sodium and potassium hypophosphites in 1 fluidrachm of finished elixir, and is used as an alternative.

Average dose: 8 Cc. (2 fluidrachms).

ELIXIR HYPOPHOSPHITUM CUM FERRO. N. F.**Elixir of Hypophosphites with Iron**

The formula for this elixir does not differ from that of the 2d ed. N. F., except the slight increase in the quantity of potassium hypophosphite and the replacement of citric acid by hypophosphorous acid. It is made from calcium, sodium and potassium hypophosphites, ferrous sulphate, hypophosphorous acid, water, syrup and aromatic elixir. It contains $\frac{1}{2}$ grain each of potassium and ferrous hypophosphites and 1 grain each of calcium and sodium hypophosphites in 1 fluidrachm of finished elixir. It is used as an alternative and chalybeate.

Average dose: 8 Cc. (2 fluidrachms).

ELIXIR LITHII BROMIDI. N. F.**Elixir of Lithium Bromide**

The formula for this elixir does not differ from that of the 2d ed. N. F., except that the citric acid used in the 2d ed. was dropped. It contains 5 grains of lithium bromide in 1 fluidrachm of finished elixir. It is used in the treatment of gout and rheumatism.

Average dose: 8 Cc. (2 fluidrachms).

ELIXIR LITHII CITRATIS. N. F.**Elixir of Lithium Citrate**

The formula for this elixir does not differ from that of the 2d ed. N. F. It contains 5 grains of lithium citrate in 1 fluidrachm of finished elixir, and is used in the treatment of gout and rheumatism.

Average dose: 6 Cc. ($1\frac{1}{2}$ fluidrachms).

ELIXIR LITHII SALICYLATIS. N. F.**Elixir of Lithium Salicylate**

The formula for this elixir does not differ from that of the 2d ed. N. F. It contains 5 grains of lithium salicylate in 1 fluidrachm of finished elixir, and is used in the treatment of gout and rheumatism.

Average dose: 8 Cc. (2 fluidrachms).

ELIXIR MALTI ET FERRI. N. F.**Elixir of Malt and Iron**

The formula for this elixir does not differ from that of the 2d ed. N. F., except that the word "soluble" has been added to ferric phosphate. It contains 1 grain of soluble ferric phosphate and 15 minims of extract of malt in 1 fluidrachm of finished elixir, and is used as a nutrient and in anæmic conditions.

Average dose: 16 Cc. (4 fluidrachms).

ELIXIR PARALDEHYDI. N. F.**Elixir of Paraldehyde**

(25 per cent.)

The formula for this elixir does not differ from that of the 2d ed. N. F. It is made from paraldehyde, glycerin, alcohol, tincture of cardamom, oils of orange and cinnamon, compound tincture of cudbear and aromatic elixir. It contains about 15 minims of paraldehyde in 1 fluidrachm of finished elixir, and is used as a hypnotic and sedative.

Average dose: 8 Cc. (2 fluidrachms).

ELIXIR PEPSINI. N. F.**Elixir of Pepsin**

The formula for this elixir was materially changed in the 3d ed. N. F., glycerite of pepsin replacing pepsin and aromatic elixir replacing compound elixir of taraxacum. It contains about 1 grain of pepsin in 1 fluidrachm of finished elixir. It is used to aid digestion.

Average dose: 8 Cc. (2 fluidrachms).

ELIXIR PEPSINI, BISMUTHI ET STRYCHNINÆ. N. F.**Elixir of Pepsin, Bismuth and Strychnine**

The formula for this elixir was changed in the 3d ed. N. F. by the addition of a trace of tartaric acid and the use of strychnine alkaloid instead of strychnine sulphate. It contains 1-100th of a grain of strychnine, $\frac{1}{2}$ grain of pepsin and 2 grains of bismuth and sodium tartrate in 1 fluidrachm of finished elixir. It is used as a tonic in dyspepsia.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR PEPSINI ET BISMUTHI. N. F.**Elixir of Pepsin and Bismuth**

The formula for this preparation was entirely changed in the 3d ed. N. F., the glycerite of bismuth replacing bismuth and ammonium citrate and ammonia water, and the glycerite of pepsin replacing pepsin. Aromatic elixir replaces compound elixir of taraxacum. It contains about $\frac{1}{2}$ grain of pepsin and 2 grains of bismuth and sodium tartrate in 1 fluidrachm of finished elixir. It is used as a digestant.

Average dose: 8 Cc. (2 fluidrachms).

ELIXIR PEPSINI ET FERRI. N. F.**Elixir of Pepsin and Iron**

The formula for this elixir does not differ from that of the 2d ed. N. F. It contains $\frac{1}{2}$ grain of ferric chloride and nearly 1 grain of pepsin in one fluidrachm of the finished elixir. It is used as a chalybeate and digestive.

Average dose: 8 Cc. (2 fluidrachms).

ELIXIR PHOSPHORI. N. F.**Elixir of Phosphorus**

This elixir was official in the U. S. P. 1890, and was introduced into the 3d ed. N. F. It is made from spirit of phosphorus, oil of anise, glycerin and aromatic elixir. About 1-60th of a grain of phosphorus is contained in 1 fluidrachm of the finished elixir. It is used as an aphrodisiac and nervous stimulant.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR PHOSPHORI ET NUCIS VOMICÆ. N. F.**Elixir of Phosphorus and Nux Vomica**

The formula for this elixir was slightly changed in the 3d ed. N. F., the quantity of nux vomica being slightly decreased. About 2 minims of tincture of nux vomica and about 1-60th of a grain of phosphorus are represented in 1 fluidrachm of the finished elixir. It is used as a tonic and stimulant to the nerves.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR PICIS COMPOSITUM. N. F.**Compound Elixir of Tar**

The formula for this elixir was greatly improved in the 3d ed. by dropping methyl alcohol and using ethyl alcohol in its place. Methyl alcohol should never be used in any pharmaceutical preparation. The elixir contains about 1-50th of a grain of morphine sulphate in 1 fluidrachm of finished elixir, with syrup of wild cherry, syrup of tolu, and wine of tar, alcohol and water. It is used as an expectorant and sedative.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR PILOCARPI. N. F.**Elixir of Pilocarpus [Elixir of Jaborandi]**

The formula for this elixir does not differ from that of the 2d ed. N. F. It is made from fluidextract of pilocarpus, syrup of coffee, tincture of vanilla and compound elixir of taraxacum, and represents about 3 $\frac{1}{2}$ grains of pilocarpus in 1 fluidrachm of the finished elixir. It is used as a diaphoretic.

Average dose: 8 Cc. (2 fluidrachms).

ELIXIR POTASSII ACETATIS. N. F.**Elixir of Potassium Acetate**

The formula for this elixir does not differ from that of the 2d ed. N. F. It contains about 5 grains of potassium acetate in 1 fluidrachm of finished elixir, and is used as a diuretic.

Average dose: 16 Cc. (4 fluidrachms).

ELIXIR POTASSII ACETATIS ET JUNIPERI. N. F.

Elixir of Potassium Acetate and Juniper

This formula does not differ from that of the 2d ed. N. F., except the replacing of magnesium carbonate by purified tale. It is made from potassium acetate, fluidextract of juniper, purified tale and aromatic elixir, and 5 grains of potassium acetate and $7\frac{1}{2}$ grains of juniper are represented in 1 fluidrachm of the finished elixir. It is used as a diaphoretic.

Average dose: 16 Cc. (4 fluidrachms).

ELIXIR POTASSII BROMIDI. N. F.

Elixir of Potassium Bromide

The formula for this elixir does not differ from that of the 2d ed. N. F., except that citric acid was dropped. It contains about 10 grains of potassium bromide in 1 fluidrachm of the finished elixir, and is used as a nervous sedative.

Average dose: 8 Cc. (2 fluidrachms).

ELIXIR QUININÆ ET PHOSPHATUM COMPOSITUM. N. F.

Compound Elixir of Quinine and Phosphates

The formula for this elixir does not differ from that of the 2d ed. N. F., except that the word "soluble" is added to the words ferrie phosphate used in the previous edition. It is made from quinine sulphate, soluble ferrie phosphate, potassium citrate, syrup of calcium lactophosphate, water and aromatic elixir, and contains about $\frac{1}{4}$ grain of quinine sulphate, 1 grain of soluble ferrie phosphate, and about $\frac{3}{4}$ of a grain of calcium lactophosphate in 1 fluidrachm of finished elixir. It is used as a tonic.

Average dose: 8 Cc. (2 fluidrachms).

ELIXIR QUININÆ VALERIANATIS ET STRYCHNINÆ. N. F.

Elixir of Quinine Valerianate and Strychnine

The formula for this elixir does not differ from that of the 2d ed. N. F. It is made from quinine valerate, strychnine sulphate, compound tincture of cudbear, and aromatic elixir, and contains 1 grain of quinine valerate and 1-100th of a grain of strychnine sulphate in 1 fluidrachm of finished elixir. It is used as a tonic and sedative in nervous affections.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR RHAMNI PURSHIANÆ. N. F.

Elixir of Cascara Sagrada Elixir of Rhamnus Purshiana

The formula for this elixir was materially changed in the 3d ed. N. F. The quantity of fluidextract of cascara sagrada was doubled, the U. S. P. (8th. Rev.) aromatic fluidextract of cascara sagrada is used, and aromatic elixir

takes the place of compound elixir of taraxacum. About 30 grains of cascara sagrada are represented in 1 fluidrachm of the finished elixir. It is used as a laxative.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR RHAMNI PURSHIANÆ COMPOSITUM. N. F.

Compound Elixir of Cascara Sagrada [Elixir Laxativum, Laxative Elixir]

The formula for this elixir was materially changed, the new U. S. P. (8th Rev.) aromatic fluidextract of cascara sagrada replacing the fluidextract of cascara sagrada used in the 2d ed. N. F., and aromatic elixir replacing compound elixir of taraxacum. It contains in addition the fluidextracts of senna and juglans, as in the 2d ed. It is used as a laxative.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR RHEI. N. F.

Elixir of Rhubarb

The formula for this elixir does not differ from that of the 2d ed. N. F. Sweet tincture of rhubarb (U. S. P. 1890) is mixed with alcohol, water, glycerin and syrup. About $2\frac{1}{4}$ grains of rhubarb are represented in 1 fluidrachm of the finished elixir. It is used as a laxative.

Average dose: 8 Cc. (2 fluidrachms).

ELIXIR RHEI ET MAGNESII ACETATIS. N. F.

Elixir of Rhubarb and Magnesium Acetate [Elixir Rhei et Magnesiae, Elixir of Rhubarb and Magnesia]

The formula for this elixir does not differ from that of the 2d ed. N. F. It is made from calcined magnesia, acetic acid, fluidextract of rhubarb and aromatic elixir, and contains about 4 grains of magnesium acetate and $7\frac{1}{2}$ grains of rhubarb in 1 fluidrachm of finished elixir. It is used as a laxative.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR RUBI COMPOSITUM. N. F.

Compound Elixir of Blackberry

The formula for this elixir does not differ from that of the 2d ed. N. F. It contains blackberry juice and blackberry root, galls, cinnamon, cloves, mace and ginger, with syrup, glycerin and diluted alcohol. It is used in the treatment of diarrhoea.

Average dose: 16 Cc. (4 fluidrachms).

ELIXIR SODII BROMIDI. N. F.

Elixir of Sodium Bromide

The formula for this elixir does not differ from that of the 2d ed. N. F., except that the citric acid was dropped. About 10 grains of

sodium bromide are represented in 1 fluidrachm of finished elixir. It is used as a sedative for the nerves.

Average dose: 8 Cc. (2 fluidrachms).

ELIXIR SODII HYPOPHOSPHITIS. N. F.

Elixir of Sodium Hypophosphite

The formula for this elixir does not differ from that of the 2d ed. N. F., except that citric acid was replaced by hypophosphorous acid. Two grains of sodium hypophosphite are represented in 1 fluidrachm of the finished elixir. It is used as an alternative.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR SODII SALICYLATIS. N. F.

Elixir of Sodium Salicylate

The formula for this elixir does not differ from that of the 2d ed. N. F. Five grains of sodium salicylate are represented in 1 fluidrachm of the finished elixir. It is used in the treatment of rheumatism.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR STILLINGIÆ COMPOSITUM. N. F.

Compound Elixir of Stillingia

The formula for this elixir does not differ from that of the 2d ed. N. F. Fifteen minims of compound fluidextract of stillingia are represented in 1 fluidrachm of the finished elixir. It is used as an alternative.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR STRYCHNINÆ VALERIANATIS. N. F.

Elixir of Strychnine Valerianate

The formula for this elixir does not differ from that of the 2d ed. N. F. It is made from strychnine valerate, acetic acid, tincture of vanilla, compound tincture of cudbear and aromatic elixir, and contains 1-100th grain of strychnine valerate in 1 fluidrachm of the finished elixir. It is used as a nerve.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR TARAXACI COMPOSITUM. N. F.

Compound Elixir of Taraxacum

In the 3d ed. N. F. very little change was made in the formula for this elixir, the new tincture of sweet orange peel replacing the U. S. P. 1890 tincture, and the quantity of the tincture of cinnamon being increased (the strength of the new tincture is 20 per cent.). It is made from fluidextracts of taraxacum, wild cherry and licorice, with the tinctures of sweet orange peel and cinnamon, compound tincture of cardamom and aromatic elixir, and is used mainly as a vehicle to cover the taste of bitter substances.

Average dose: 8 Cc. (2 fluidrachms).

ELIXIR TERPINI HYDRATIS. N. F.

Elixir of Terpin Hydrate

This is a new elixir introduced into the 3d ed. N. F. It contains terpin hydrate, tincture of sweet orange peel, solution of saccharin, alcohol, glycerin and syrup. The solution of saccharin might well have been omitted. About 1 grain of terpin hydrate is contained in 1 fluidrachm of the finished elixir. It is used as a stimulant and expectorant.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR TERPINI HYDRATIS CUM CODEINA. N. F.

Elixir of Terpin Hydrate with Codeine

This is a new elixir introduced into the 3d ed. N. F. It contains about 1 grain of terpin hydrate and $\frac{1}{2}$ grain of codeine in 1 fluidrachm of the finished elixir. It is used as an expectorant and sedative.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR TERPINI HYDRATIS CUM HEROINA. N. F.

Elixir of Terpin Hydrate with Heroine

This is a new elixir introduced into the 3d ed. N. F. It contains 1 grain of terpin hydrate and 1-24th of a grain of heroine in 1 fluidrachm of the finished elixir. It is used as an expectorant and sedative.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR TURNERÆ. N. F.

Elixir of Turnera [Elixir of Damiana]

The formula for this elixir does not differ from that of the 2d ed. N. F., except in the replacement of magnesium carbonate by purified talc. It is made from fluidextract of turnera, purified talc, alcohol, glycerin and aromatic elixir. About $9\frac{1}{2}$ grains of turnera are represented in 1 fluidrachm of the finished elixir. It is used as an aphrodisiac.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR VIBURNI OPULI COMPOSITUM. N. F.

Compound Elixir of Viburnum Opulus [Compound Elixir of Crampbark]

The formula for this elixir does not differ from that of 2d ed. N. F. About $4\frac{1}{2}$ grains each of viburnum opulus and aletris and $9\frac{1}{2}$ grains of trillium with compound elixir of taraxacum are represented in 1 fluidrachm of the finished elixir. It is used as an antispasmodic.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR VIBURNI PRUNIFOLII. N. F.

Elixir of Viburnum Prunifolium
[Elixir of Black Haw]

The formula for this elixir does not differ from that of the 2d ed. N. F. It is made from fluidextract of viburnum prunifolium, compound tincture of cardamom, and aromatic elixir, and contains about $7\frac{1}{2}$ grains of viburnum prunifolium in 1 fluidrachm of the finished elixir. It is used as an antispasmodic and sedative.

Average dose: 4 Cc. (1 fluidrachm).

ELIXIR ZINCI VALERIANATIS. N. F.

Elixir of Zinc Valerianate

The formula for this elixir does not differ from that of the 2d ed. N. F. It is made from zinc valerate, stronger solution of ammonium citrate, alcohol, spirit of bitter almond, compound tincture of cudbear, and aromatic elixir. About 1 grain of zinc valerate is represented in 1 fluidrachm of the finished elixir. It is used as a nervine.

Average dose: 4 Cc. (1 fluidrachm).

EMPLASTRUM AROMATICUM. N. F.

Aromatic Plaster [Spice Plaster]

The formula for this plaster does not differ from that of the 2d ed. N. F., except that parts are substituted for grammes. It is made from cloves, ginger, cinnamon, capsicum, camphor, cotton seed oil and lead plaster. It is used as a counter-irritant and rubefacient.

EMPLASTRUM FUSCUM CAMPHORATUM. N. F.

Camphorated Brown Plaster [Emplastrum Matris Camphoratum, Camphorated Mother Plaster]

The formula for this plaster has not been changed from that of the 2d ed. N. F., except that parts are substituted for grammes. It is made from red oxide of lead, olive oil, yellow wax and camphor. Used as a discutient.

EMPLASTRUM PICIS LIQUIDÆ COMPOSITUM. N. F.

Compound Tar Plaster

The formula for this plaster was changed in the 3d ed. N. F. only by using parts for grammes. It is made from rosin, tar, powdered podophyllum, powdered phytolacca root and powdered sanguinaria, and is used as a rubefacient and counter-irritant.

EMULSUM OLEI MORRHUÆ CUM CALCII ET SODII PHOSPHATIBUS. N. F.

Emulsion of Cod-Liver Oil with Calcium and Sodium Phosphates [Emulsion of Cod-Liver Oil with Phosphates of Lime and Soda]

The formula for this emulsion does not differ from that of the 2d ed. N. F. In the Latin title the word "Emulsio" has been changed to "Emulum" in this class of preparations. It contains 50 per cent. of cod liver oil, with calcium and sodium phosphates, syrup of tolu and flavoring. It is used as an alternative.

Average dose: 16 Cc. (4 fluidrachms).

EMULSUM OLEI MORRHUÆ CUM CALCII LACTOPHOSPHATE. N. F.

Emulsion of Cod-Liver Oil with Calcium Lactophosphate [Emulsion of Cod-Liver Oil with Lactophosphate of Lime]

The formula for this emulsion does not differ from that of the 2d ed. N. F. It contains 50 per cent. of cod liver oil, with calcium lactate, phosphoric acid, syrup of tolu and flavoring. It is used as an alternative.

Average dose: 16 Cc. (4 fluidrachms).

EMULSUM OLEI MORRHUÆ CUM CALCII PHOSPHATE. N. F.

Emulsion of Cod-Liver Oil with Calcium Phosphate [Emulsion of Cod-Liver Oil with Phosphate of Lime]

The formula for this emulsion does not differ from that of the 2d ed. N. F. It contains 50 per cent. of cod liver oil, with calcium phosphate, syrup of tolu and flavoring. Used as an alternative.

Average dose: 16 Cc. (4 fluidrachms).

EMULSUM OLEI MORRHUÆ CUM EXTRACTO MALTI. N. F.

Emulsion of Cod-Liver Oil with Extract of Malt

The formula for this emulsion does not differ from that of the 2d ed. N. F. It contains 50 per cent. of cod liver oil with $37\frac{1}{2}$ per cent. of extract of malt. It is used as a tonic and alternative.

Average dose: 16 Cc. (4 fluidrachms).

EMULSUM OLEI MORRHUÆ CUM PRUNO VIRGINIANA. N. F.

Emulsion of Cod-Liver Oil with Wild Cherry

The formula for this emulsion does not differ from that of the 2d ed. N. F. It contains 50

per cent. of cod liver oil with fluidextract of wild cherry, syrup of tolu and flavoring. It is used as an alternative.

Average dose: 16 Cc. (4 fluidrachms).

EMULSUM OLEI RICINI. N. F.

Emulsion of Castor Oil

The formula for this emulsion does not differ from that of the 2d ed. N. F. It contains 33 per cent. of castor oil, with tincture of vanilla, syrup and water. It is used as a cathartic.

Average dose: 48 Cc. (1½ fluidounces).

EMULSUM OLEI TEREBINTHINÆ FOR- TIOR. N. F.

Stronger Emulsion of Oil of Turpentine [Forbes's Emulsion of Oil of Turpentine]

The formula for this emulsion does not differ from that of the 2d ed. N. F. It contains 50 per cent. of oil of turpentine, with acacia and water. It is used as an anthelmintic and diuretic.

Average dose: 2 Cc. (½ fluidrachm).

EMULSUM PETROLEI. N. F.

Emulsion of Petroleum

This new emulsion of the 3d ed. N. F. should have been called Emulsion of Petrolatum, instead of Emulsion of Petroleum. It contains about 5 per cent. of white petrolatum, about 25 per cent. of expressed oil of almond, with acacia, tragacanth and syrup, tincture of lemon peel and water.

Average dose: 16 Cc. (4 fluidrachms).

EMULSUM PHOSPHATICUM. N. F.

Phosphatic Emulsion [Mistura Phosphatica]

The formula for this emulsion does not differ from that of the 2d ed. N. F. It contains 25 per cent. of cod liver oil, 5 per cent. of diluted phosphoric acid, with glycerite of yolk of egg, Jamaica rum, oil of bitter almond and orange flower water. Used as an alternative.

Average dose: 16 Cc. (4 fluidrachms).

ESSENTIA PEPSINI. N. F.

Essence of Pepsin

This is a new preparation of the 3d ed. N. F. It contains pepsin, rennin (an enzyme from calves' rennets), lactic acid, tincture of sweet orange peel, glycerin, alcohol, syrup, white wine and water. It is used as an aid to digestion.

Average dose: 8 Cc. (2 fluidrachms).

(113)

EXTRACTUM FERRI POMATUM. N. F.

Ferrated Extract of Apples

[Ferri Malas Crudas, Crude Malate of Iron]

This formula does not differ from that of the 2d ed. N. F. It is made from iron wire, ripe sour apples and water, and is used as a chalybeate.

Average dose: 0.65 Gm. (10 grains).

EXTRACTUM GLYCYRRHIZÆ DEPU- RATUM. N. F.

Purified Extract of Glycyrrhiza

Purified Extract of Licorice

The formula for this preparation does not differ from that of the 2d ed. N. F. This is a pilular extract made by the old German method and not to be confounded with the Extractum Glycyrrhizæ Purum, U. S. P. 8th Rev. Used as a flavoring and sweetening agent.

Average dose: 1 Gm. (15 grains).

FERRI HYPOPHOSPHIS. N. F.

Hypophosphite of Iron [Ferric Hypophos- phite]

Ferric hypophosphite is now official in the U. S. P. 8th Rev., without a formula for its preparation. The process in the 3d ed. N. F. is the same as that found in the 2d ed. N. F. It is made from ferric ammonium sulphate, sodium hypophosphite and distilled water. It is used as an alternative and chalybeate.

Average dose: 0.2 Gm. (3 grains).

FLUIDEXTRACTUM ADONIDIS. N. F.

Fluidextract of Adonis

From the root of *Adonis vernalis* Linné (Bird's Eye).

Made with alcohol, 1 Cc. of fluidextract representing 1 Gm. of the drug. It is used as a heart stimulant.

Average dose: 0.13 Cc. (2 minims).

FLUIDEXTRACTUM ALETRIDIS. N. F.

Fluidextract of Aletris

From the rhizome of *Aletris farinosa* Linné (Stargrass).

Made with diluted alcohol, 1 Cc. of fluidextract representing 1 Gm. of the drug. It is used as an alternative.

Average dose: 2 Cc. (30 minims).

FLUIDEXTRACTUM ANGELICÆ RADICIS. N. F.

Fluidextract of Angelica Root

From the root of *Angelica Archangelica* Linné (Angelica).

Made with alcohol 3 measures, water 2 measures; 1 Cc. of fluidextract represents 1 Gm. of the drug. It is used as a stimulant and carminative.

Average dose: 2 Cc. (30 minims).

FLUIDEXTRACTUM APII GRAVEOLENTIS. N. F.

Fluidextract of Celery

From the seed of *Apium graveolens* Linné (Celery).

Made with alcohol 2 measures, water 1 measure; 1 Cc. of fluidextract represents 1 Gm. of the drug. It is used as a diuretic and nervine.

Average dose: 2 Cc. (30 minims).

FLUIDEXTRACTUM ARALIAE RACEMOSÆ. N. F.

Fluidextract of Aralia Racemosa

From the root of *Aralia racemosa* Linné (American Spikenard).

Made with alcohol 2 measures, water 1 measure; 1 Cc. of fluidextract represents 1 Gm. of the drug. It is used as an alterative.

Average dose: 2 Cc. (30 minims).

FLUIDEXTRACTUM ARNICÆ FLORUM. N. F.

Fluidextract of Arnica Flowers

From the flower heads of *Arnica montana* Linné (Arnica).

Made with diluted alcohol, 1 Cc. of fluidextract representing 1 Gm. of the drug. It is used as a stimulant and alterative.

Average dose: 1 Cc. (15 minims).

FLUIDEXTRACTUM BOLDI. N. F.

Fluidextract of Boldo

From the leaves of *Peumus Boldus* Molina (Boldo).

Made with alcohol 2 measures, water 1 measure; 1 Cc. represents 1 Gm. of the drug. It is used as an alterative and tonic.

Average dose: 0.5 Cc. (8 minims).

FLUIDEXTRACTUM BUCHU COMPOSITUM. N. F.

Compound Fluidextract of Buchu

Made with alcohol 2 measures, water 1 measure. It contains buchu, cubeb, juniper and uva ursi. It is used as a diuretic.

Average dose: 2 Cc. (30 minims).

FLUIDEXTRACTUM CALENDULÆ. N. F. Fluidextract of Calendula

From the flowering herb of *Calendula officinalis* Linné (Marigold).

Made with alcohol 2 measures, water 1 measure; 1 Cc. of fluidextract represents 1 Gm. of the drug. It is used as a stimulant and tonic.

Average dose: 1 Cc. (15 minims).

FLUIDEXTRACTUM CAMELLIÆ. N. F. Fluidextract of Camellia

From the commercial dried leaves of *Camellia Thea* Link (Tea).

Made with alcohol 250 Cc., water 685 Cc., glycerin 65 Cc., finishing with alcohol 1 measure, water 3 measures; 1 Cc. of fluidextract represents 1 Gm. of drug. It is used as a nerve stimulant.

Average dose: 2 Cc. (30 minims).

FLUIDEXTRACTUM CAULOPHYLLI. N. F.

Fluidextract of Caulophyllum

From the rhizome and rootlets of *Caulophyllum thalictroides* Michaux (Blue Cohosh).

Made with alcohol 3 measures, water 1 measure; 1 Cc. of fluidextract represents 1 Gm. of drug. It is used as an emmenagogue.

Average dose: 0.5 Cc. (8 minims).

FLUIDEXTRACTUM COFFÆ TOSTÆ. N. F.

Fluidextract of Roasted Coffee

From the commercial roasted seeds of *Coffea arabica* Linné (Coffee).

Made with alcohol 250 Cc., water 685 Cc., glycerin 65 Cc., finishing with alcohol 1 measure, water 3 measures; 1 Cc. of fluidextract represents 1 Gm. of drug. It is used as a nerve stimulant.

Average dose: 2 Cc. (30 minims).

FLUIDEXTRACTUM COFFÆ VIRIDIS. N. F.

Fluidextract of Green Coffee

From the commercial, unroasted seeds of *Coffea arabica* Linné (Coffee).

Made with alcohol 250 Cc., water 685 Cc., glycerin 65 Cc., finishing with alcohol 1 measure, water 3 measures; 1 Cc. of fluidextract represents 1 Gm. of drug. It is used as a nerve stimulant.

Average dose: 2 Cc. (30 minims).

FLUIDEXTRACTUM CONVALLARIÆ. N. F.

Fluidextract of Convallaria Flowers

From the flowers of *Convallaria majalis* Linné (Lily of the Valley).

The word "Florum" has been dropped from the Latin title of this fluidextract. Made with diluted alcohol, 1 Cc. of fluidextract representing 1 Gm. of the drug. It is used as a cardiac stimulant and diuretic.

Average dose: 0.5 Cc. (8 minims).

FLUIDEXTRACTUM COPTIS. N. F.**Fluidextract of Coptis**

From the rhizome and rootlets of *Coptis trifolia* Salisbury (Goldthread).

Made with diluted alcohol, 1 Cc. of fluidextract representing 1 Gm. of the drug. It is used as a tonic and stimulant.

Average dose: 2 Cc. (30 minims).

FLUIDEXTRACTUM CORNUS. N. F.**Fluidextract of Cornus**

From the bark of the root of *Cornus Florida* Linné (Dogwood).

Made with glycerin 150 Cc., diluted alcohol 850 Cc., finishing with diluted alcohol; 1 Cc. of fluidextract represents 1 Gm. of drug. It is used as a tonic.

Average dose: 2 Cc. (30 minims).

FLUIDEXTRACTUM CORNUS CIRGINATÆ. N. F.**Fluidextract of Cornus Circinata**

From the bark of *Cornus circinata* L'Héritier (Green Osier).

Made with diluted alcohol, 1 Cc. of fluidextract representing 1 Gm. of drug. It is used as a tonic and antiperiodic.

Average dose: 1 Cc. (15 minims).

FLUIDEXTRACTUM CORYDALIS. N. F.**Fluidextract of Corydalis**

From the tubers of *Dicentra canadensis* De Candolle (Turkey Corn).

Made with alcohol 3 measures, water 1 measure; 1 Cc. of fluidextract represents 1 Gm. of drug. It is used as an alterative and diuretic.

Average dose: 0.65 Cc. (10 minims).

FLUIDEXTRACTUM COTO. N. F.**Fluidextract of Coto**

From Coto bark, derived from an undetermined tree, native of tropical South America.

Made with alcohol 9 measures, water 1 measure; 1 Cc. of fluidextract represents 1 Gm. of drug. It is used as an astringent and tonic.

Average dose: 0.3 Cc. (5 minims).

FLUIDEXTRACTUM FUCI. N. F.**Fluidextract of Fucus**

From the thallus of *Fucus vesiculosus* Linné (Bladder-wrack).

Made with alcohol 3 measures, water 1 measure; 1 Cc. of fluidextract represents 1 Gm. of drug. It is used as a remedy for obesity.

Average dose: 0.65 Cc. (10 minims).

FLUIDEXTRACTUM HELIANTHEMI. N. F.**Fluidextract of Helianthemum**

From the herb of *Helianthemum canadense* Michaux (Frost-wort).

Made with diluted alcohol, 1 Cc. of fluidextract representing 1 Gm. of drug. It is used as an alterative and astringent.

Average dose: 4 Cc. (1 fluidrachm).

FLUIDEXTRACTUM HUMULI. N. F.**Fluidextract of Hops**

From the strobiles of *Humulus Lupulus* Linné (Hops).

Made with alcohol 5 measures, water 3 measures; 1 Cc. of fluidextract represents 1 Gm. of drug. It is used as a stimulant and sedative.

Average dose: 2 Cc. (30 minims).

FLUIDEXTRACTUM HYDRANGEÆ. N. F.**Fluidextract of Hydrangea**

From the root of *Hydrangea arborescens* Linné (Seven Barks).

Made with alcohol 3 measures, water 2 measures; 1 Cc. of fluidextract represents 1 Gm. of drug. It is used as a diuretic.

Average dose: 2 Cc. (30 minims).

FLUIDEXTRACTUM JALAPÆ. N. F.**Fluidextract of Jalap**

From the tuberous root of *Exogonium Purga* Bentham (Jalap).

Made with alcohol, 1 Cc. of fluidextract representing 1 Gm. of drug. It is used as a cathartic.

Average dose: 1 Cc. (15 minims).

FLUIDEXTRACTUM JUGLANDIS. N. F.**Fluidextract of Juglans**

From the inner bark of the root of *Juglans cinerea* Linné (Butternut).

Made with diluted alcohol; 1 Cc. of fluidextract represents 1 Gm. of drug. It is used as a cathartic.

Average dose: 4 Cc. (1 fluidrachm).

FLUIDEXTRACTUM JUNIPERI. N. F.**Fluidextract of Juniper**

From the fruit of *Juniperus communis* Linné (Juniper).

Made with diluted alcohol; 1 Cc. of fluidextract represents 1 Gm. of drug. It is used as a diuretic.

Average dose: 4 Cc. (1 fluidrachm).

FLUIDEXTRACTUM KAVÆ. N. F.**Fluidextract of Kava**

From the root of *Piper methysticum* Forster (Kava; Kava-kava; Ava).

Made with alcohol 3 measures, water 2 measures; 1 Cc. of fluidextract represents 1 Gm. of drug. It is used as a diuretic and alternative.
Average dose: 1 Cc. (15 minims).

FLUIDEXTRACTUM MALTI. N. F.

Fluidextract of Malt

This formula does not differ from that of the 2d ed. N. F. It is used as a tonic.
Average dose: 8 Cc. (2 fluidrachms).

FLUIDEXTRACTUM MENYANTHIS. N. F.

Fluidextract of Menyanthes

From the leaves of *Menyanthes trifoliata* Linné (Buckbean.—*Trifolium fibrinum* G. P.)
 Made with diluted alcohol; 1 Cc. of fluidextract represents 1 Gm. of drug. It is used as an alternative.

Average dose: 1 Cc. (15 minims).

FLUIDEXTRACTUM PETROSELINI RADICIS. N. F.

Fluidextract of Parsley Root

From the root of *Petroselinum sativum* Hoffmann (Parsley).

Made with diluted alcohol; 1 Cc. of fluidextract representing 1 Gm. of drug. It is used as an emmenagogue and diuretic.

Average dose: 2 Cc. (30 minims).

FLUIDEXTRACTUM RHAMNI PURSHI- ANÆ ALKALINUM. N. F.

Bitterless Fluidextract of Cascara Sagrada

This is a new fluidextract in the 3d ed. N. F. It is made from cascara sagrada deprived of its bitterness by treatment with lime; the preparation contains sugar, oil of coriander and oil of anise. It differs from all other fluidextracts in containing no alcohol, and is really a syrup. It is used as a laxative.

Average dose: 1 Cc. (15 minims).

FLUIDEXTRACTUM STERCULIÆ. N. F.

Fluidextract of Sterculia

From the seeds of *Sterculia acuminata* R. Brown (Cola; Kola).

Made with alcohol 250 Cc., water 685 Cc., glycerin 65 Cc., finishing with alcohol 1 measure, water 3 measures. One Cc. of fluidextract represents 1 Gm. of drug. It is used as a stimulant and nerve tonic.

Average dose: 1 Cc. (15 minims).

FLUIDEXTRACTUM STILLINGIÆ COMPOSITUM. N. F.

Compound Fluidextract of Stillingia

The formula for this fluidextract has been slightly changed in the 3d ed. N. F., the quantity of coriander being decreased, and that of xanthoxylum berries increased.

Made with alcohol 500 Cc., water 250 Cc., glycerin 250 Cc., finishing with diluted alcohol. It contains stillingia, corydalis, iris, sambucus, chimaphila, coriander and xanthoxylum berries. It is used as an alternative.

Average dose: 2 Cc. (30 minims).

FLUIDEXTRACTUM TRILLII. N. F.

Fluidextract of Trillium

From the rhizome of *Trillium erectum* Linné, and other species of *Trillium* (Bethroot).

Made with alcohol 3 measures, water 2 measures; 1 Cc. of fluidextract represents 1 Gm. of drug. It is used as an astringent and tonic expectorant.

Average dose: 2 Cc. (30 minims).

FLUIDEXTRACTUM TURNERÆ. N. F.

Fluidextract of Turnera

From the leaves of *Turnera microphylla* De Candolle, and other species of *Turnera* (Damiana).

Made with alcohol 2 measures, water 1 measure; 1 Cc. of fluidextract represents 1 Gm. of drug. It is used as an aphrodisiac.

Average dose: 2 Cc. (30 minims).

FLUIDEXTRACTUM URTICÆ. N. F.

Fluidextract of Urtica

From the root of *Urtica dioica* Linné (Nettle).

Made with diluted alcohol; 1 Cc. of fluidextract represents 1 Gm. of drug. It is used as a diuretic and astringent.

Average dose: 1 Cc. (15 minims).

FLUIDEXTRACTUM VERBASCI. N. F.

Fluidextract of Verbascum

From the leaves and flowers of *Verbascum Thapsus* Linné (Mullein).

Made with diluted alcohol; 1 Cc. of fluidextract represents 1 Gm. of drug. It is used as an expectorant.

Average dose: 4 Cc. (1 fluidrachm).

FLUIDEXTRACTUM VERBENÆ. N. F.

Fluidextract of Verbena

From the root of *Verbena hastata* Linné (Vervain).

Made with diluted alcohol; 1 Cc. of fluidextract represents 1 Gm. of drug. It is used as a tonic.

Average dose: 1 Cc. (15 minims).

FLUIDEXTRACTUM ZEÆ. N. F.**Fluidextract of Zea**

[**Extractum Stigmatum Maydis Fluidum,**
Fluidextract of Corn Silk]

From the stigmata of *Zea Mays* Linné (Indian Corn).

Made with diluted alcohol; 1 Ce. of fluid-extract represents 1 Gm. of drug. It is used as a diuretic.

Average dose: 4 Ce. (1 fluidrachm).

GELATINUM CHONDRI. N. F.**Irish Moss Gelatin**

The formula for this preparation does not differ from that of the 2d ed. N. F. It is made from Irish moss and water, and is used to make a transparent mucilage, and as a substitute for acacia in making emulsions.

GLYCERITUM BISMUTHI. N. F.**Glycerite of Bismuth**

The formula for this preparation was entirely changed in the 3d ed. N. F. The glycerite is made from bismuth subnitrate, nitric acid, tartaric acid, sodium bicarbonate, glycerin and distilled water. It contains 16 grains of bismuth and sodium tartrate in 1 fluidrachm of the finished glycerite, and is used in making other N. F. preparations containing bismuth and in the treatment of diarrhœa and gastric diseases.

Average dose: 0.6 Ce. (10 minims).

GLYCERITUM GUAIACI. N. F.**Glycerite of Guaiac**

The formula for this glycerite does not differ from that of the 2d ed. N. F. It contains 5 grains of guaiac and about 4 minims of solution of potassium hydroxide in 1 fluidrachm of the finished glycerite. It is used as an alterative.

Average dose: 2 Ce. (30 minims).

GLYCERITUM PEPSINI. N. F.**Glycerite of Pepsin**

The formula for this glycerite does not differ from that of the 2d ed. N. F. Five grains of pepsin are represented by 1 fluidrachm of the finished glycerite. It is used as a digestive.

Average dose: 3 Ce. (45 minims).

GLYCERITUM PICIS LIQUIDÆ. N. F.**Glycerite of Tar**

The quantity of tar in this glycerite was very slightly reduced in the 3d ed. N. F. It is made from tar, magnesium carbonate, glycerin, alco-

hol and water. The medicinal virtues of about 4 grains of tar are represented in 1 fluidrachm of the finished glycerite. It is used as an expectorant.

Average dose: 4 Ce. (1 fluidrachm).

GLYCERITUM TRAGACANTHÆ. N. F.**Glycerite of Tragacanth**

The formula for this glycerite does not differ from that of the 2d ed. N. F. It is used as an excipient for pills.

GLYCEROGELATINA. N. F.**Glycerogelatins**

Glycerogelatins originated with Dr. Unna and are soft masses which melt at the temperature of the body, containing gelatin, glycerin, water and the medicament. They are used in skin diseases. The following were adopted by the 3d ed. N. F.

1. *Glycerogelatinum Acidi Salicylici* (10 per cent.). N. F.—10 per cent. *Salicylic Acid Glycerogelatin.*

2. *Glycerogelatinum Iodoformi* (10 per cent.). N. F.—10 per cent. *Iodoform Glycerogelatin.*

3. *Glycerogelatinum Zinci Durum.* N. F. *Firm Zinc Glycerogelatin.*

4. *Glycerogelatinum Zinci Molle.* N. F.—*Soft Zinc Glycerogelatin.*

GOSSYPIUM STYPTICUM. N. F.**Styptic Cotton**

The formula for this preparation does not differ from that of the 2d ed. N. F. It is made by impregnating purified cotton with diluted solution of ferric chloride, glycerin and water. Used as an antihemorrhagic.

INFUSUM GENTIANÆ COMPOSITUM FORTIUS. N. F.**Stronger Compound Infusion of Gentian**

The formula for this infusion does not differ from that of the 2d ed. N. F., except a slight increase in the proportions of coriander and bitter orange peel. It is used as a tonic, and in making by dilution, compound infusion of gentian.

Average dose: 4 Ce. (1 fluidrachm).

INFUSUM ROSÆ COMPOSITUM. N. F.**Compound Infusion of Rose**

The formula for this infusion does not differ from that of the 2d ed. N. F. It is made from red rose, diluted sulphuric acid, sugar and water. It is used as an astringent.

IODOFORMUM AROMATISATUM. N. F.
Aromatized Iodoform [Deodorized Iodoform]

The formula for this preparation does not differ from that of the 2d ed. N. F. It consists of iodoform containing 4 per cent. of eumarin, and is used as an antiseptic and alterative.

LAC FERMENTATUM. N. F.
Fermented Milk [Kumyss]

The formula for this preparation does not differ from that of the 2d ed. N. F. It is made from fresh cow's milk, yeast and sugar, and is used as a food for invalids.

LAC HUMANISATUM. N. F.
Humanized Milk

This is a new preparation in the 3d ed. N. F. It is made by adding humanizing milk powder to cow's milk, cream and water. Humanizing milk powder contains pancreatin. The milk is used as a food for invalids.

LINIMENTUM ACONITI ET CHLOROFORMI. N. F.
Liniment of Aconite and Chloroform

In the 3d ed. N. F. a smaller proportion of fluidextract of aconite replaces the tincture of aconite of the 2d ed., and alcohol was added to the formula. The quantities of chloroform and soap liniment remain unchanged. It is used externally to relieve pain.

LINIMENTUM AMMONII IODIDI. N. F.
Liniment of Ammonium Iodide

The formula for this liniment does not differ from that of the 2d ed. N. F., except in a slight increase in the proportion of camphor. The liniment is made from iodine, oil of rosemary, oil of lavender, camphor, ammonia water and alcohol. It is used as an external discutient application.

LINIMENTUM IODI. N. F.
Iodine Liniment

This liniment is nearly identical with that of the British Pharmacopœia. It contains 12½ per cent. of iodine, 5 per cent. of potassium iodide, with glycerin, water and alcohol. It is used as an external discutient application.

LINIMENTUM OPII COMPOSITUM. N. F.
Compound Liniment of Opium
[Canada Liniment]

The formula for this preparation does not differ from that of the 2d ed. N. F. The liniment contains 10 per cent. of tincture of opium, with camphor, alcohol, oil of peppermint, ammonia water and oil of turpentine. It is used as a stimulating anodyne application.

LINIMENTUM SAPONATO-CAMPHORATUM. N. F.

Camphorated Soap Liniment [Opodeldoc, Solid Opodeldoc]

The formula for this preparation does not differ from that of the 2d ed. N. F. The liniment contains white castile soap, camphor, alcohol, oils of thyme and rosemary and ammonia water. It is a solid preparation used in rheumatism.

LINIMENTUM TEREBINTHINÆ ACETICUM. N. F.

Acetic Turpentine Liniment [Linimentum Album, Stokes' Liniment, St. John Long's Liniment]

The formula for this preparation does not differ from that of the 2d ed. N. F. The liniment contains turpentine, fresh egg, oil of lemon, acetic acid and rose water. It is used as a stimulating external application.

LINIMENTUM TIGLII. N. F.

Liniment of Croton Oil [Linimentum Crotonis, B. P.]

The proportions in the formula for this liniment have been slightly changed. It now contains 16 parts of croton oil, and 54 parts each of alcohol and oil of cajuput. It is used as a counter-irritant.

LINIMENTUM TIGLII COMPOSITUM. N. F.
Compound Croton Oil Liniment

The formula for this preparation does not differ from that of the 2d ed. N. F. The liniment contains 20 per cent. each of croton oil, oil of sassafras, oil of turpentine, with 40 per cent. of olive oil. It is used as a counter-irritant.

LIQUOR ALUMINI ACETATIS. N. F.
Solution of Aluminum Acetate

The formula for this solution does not differ from that of the 2d ed. N. F. It is made from aluminum sulphate, acetic acid, calcium carbonate and water, and contains from 7.5 to 8 per cent. of basic aluminum acetate. It is used externally as an astringent.

LIQUOR ALUMINI ACETICO-TARTRATIS. N. F.

Solution of Aluminum Acetico-Tartrate

The formula for this solution does not differ from that of the 2d ed. N. F.; the solution contains about 50 per cent. of dry so-called aluminum acetico-tartrate. It is made from alum, sodium carbonate, glacial acetic acid and water, and is used externally as an astringent.

LIQUOR AMMONII ACETATIS CONCENTRATUS. N. F.**Concentrated Solution of Ammonium Acetate**

The formula for this preparation does not differ from that of the 2d ed. N. F. This solution is about three times stronger than the official solution of ammonium acetate. It is intended to be diluted with carbonic acid water at the time of dispensing.

LIQUOR AMMONII CITRATIS FORTIOR. N. F.**Stronger Solution of Ammonium Citrate**

The formula for this solution does not differ from that of the 2d ed. N. F. About 40 grains of ammonium citrate are contained in 1 fluidrachm of the solution. It is intended to be diluted before administration. The Liquor Ammonii Citratis of the British Pharmacopœia may be made by mixing 1 volume of this solution with 4 volumes of water. It is used as a refrigerant and diuretic.

LIQUOR ANTIGERMINARUS. N. F.**"Germicide"**

This solution is a new one in the 3d ed. N. F. It contains thymol, oils of eucalyptus and lavender, with alcohol and water. It is used as a germicide.

LIQUOR ANTISEPTICUS ALKALINUS. N. F.**"Alkaline Antiseptic"**

This is a new solution in the 3d ed. N. F. It is made from potassium bicarbonate, sodium benzoate, sodium borate, thymol, eucalyptol, oils of peppermint and gaultheria, tincture of cudbear, alcohol, glycerin, purified tale and water. It is used as an alkaline detergent and antiseptic.

LIQUOR AURI ET ARSENI BROMIDI. N. F.**Solution of Bromide of Gold and Arsenic**

The formula for this solution does not differ from that of the 2d ed. N. F. About 1-32d of a grain of tribromide of gold and 1-16th of a grain of tribromide of arsenic are contained in 10 minims of this solution. It is used as an alterative.

Average dose: 0.2 Ce. (3 minims).

LIQUOR BISMUTHI. N. F.**Solution of Bismuth [Liquid Bismuth]**

The formula for this solution does not differ from that of the 2d ed. N. F. It is made from glycerite of bismuth, alcohol and distilled water. About 1 grain of bismuth and ammonium citrate

is represented in 1 fluidrachm of the finished solution. It is used as a sedative in gastric diseases.

Average dose: 4 Ce. (1 fluidrachm).

LIQUOR BROMI. N. F.**Solution of Bromine [Smith's Solution of Bromine]**

The formula for this solution does not differ from that of the 2d ed. N. F. One hundred Ce. of finished solution contains 25 grains of bromine and 12.5 grains of potassium bromide. It is used as an external application to hospital gangrene and as an antiseptic.

LIQUOR CALCIS SULPHURATÆ. N. F.**Solution of Sulphurated Lime [Solution of Oxysulphuret of Calcium; Vlemick's Solution, or Lotion]**

The formula for this solution does not differ from that of the 2d ed. N. F. It is made from lime, sublimed sulphur and water. It is used as an external application in skin diseases.

LIQUOR CARMINI. N. F.**Solution of Carmine**

The formula for this solution does not differ greatly from that of the 2d ed. N. F. The solution is made from carmine, ammonia water, glycerin and water. It is used as a red coloring solution.

LIQUOR COCCINEUS. N. F.**Cochineal Color**

This solution does not differ very greatly from that of the 2d ed. N. F. It is made from cochineal, potassium carbonate, alum, potassium bitartrate, alcohol and water. Like the preceding solution it is used as a red coloring solution.

LIQUOR ELECTROPOEICUS. N. F.**Battery Fluid**

The formula for battery fluid does not differ from that of the 2d ed. N. F. As indicated by the name, it is used solely in batteries.

LIQUOR EXTRACTI GLYCÝRRHIZÆ. N. F.**Solution of Extract of Glycyrrhiza [Solution of Extract of Licorice]**

The formula for this solution does not differ from that of the 2d ed. N. F. It is made from purified extract of glycyrrhiza, alcohol, glycerin and water. About 15 grains of dried extract of glycyrrhiza are represented in 1 fluidrachm of finished solution. It is used as a flavoring and sweetening agent.

Average dose: 4 Ce. (1 fluidrachm).

LIQUOR FERRI ALBUMINATI. N. F.

Solution of Albuminate of Iron

This is a new preparation in the 3d ed. N. F. It is made from fresh egg-albumen, solution of ferric oxychloride, alcohol, aromatic elixir, solution of sodium hydroxide and water. About 2-5th of a grain of metallic iron in the form of albuminate is contained in 1 fluidrachm of the finished solution. It is used as a chalybeate.

Average dose: 8 Cc. (2 fluidrachms).

LIQUOR FERRI HYPOPHOSPHITIS. N. F.

Solution of Hypophosphite of Iron [Solution of Ferric Hypophosphite]

The formula for this solution does not differ from that of the 2d ed. N. F. It is made from ferric ammonium sulphate, sodium hypophosphite, potassium citrate, glycerin and water. About 10 grains of ferric hypophosphite are represented in 1 fluidrachm of finished solution.

Average dose: 1 Cc. (15 minims).

LIQUOR FERRI IODIDI. N. F.

Solution of Ferrous Iodide

The formula for this solution does not differ from that of the 2d ed. N. F. It is made from iron wire, iodine, diluted hypophosphorous acid and distilled water. It contains about 85 per cent. of ferrous iodide. This solution was introduced for making syrup of ferrous iodide by mixing 1 volume with 15 volumes of syrup.

Average dose: 0.15 Cc. (2 minims).

LIQUOR FERRI OXYCHLORIDI. N. F.

Solution of Ferric Oxychloride

This is a new solution taken from the German Pharmacopœia, and intended to be dispensed when *Liquor Ferri Dialysati* is called for. It is made from solution of ferric chloride, ammonia water, hydrochloric acid and water. It contains about 3.5 per cent. of iron as oxychloride, and is used as a chalybeate.

LIQUOR FERRI OXYSULPHATIS. N. F.

Solution of Oxysulphate of Iron

The formula for this solution does not differ from that of the 2d ed. N. F. It is made from ferrous sulphate, nitric acid and distilled water. It is used as a chalybeate.

LIQUOR FERRI PEPTONATI. N. F.

Solution of Peptonate of Iron

This is a new preparation of the 3d ed. N. F. It is made from peptone, solution of ferric oxychloride, alcohol, aromatic elixir, solution of sodium hydroxide and distilled water. It contains about 2-5th of a grain of metallic iron in the form of peptonate in 1 fluidrachm of the finished solution. It is used as a chalybeate.

Average dose: 8 Cc. (2 fluidrachms).

LIQUOR FERRI PEPTONATI CUM MANGANO. N. F.

Solution of Peptonate of Iron with Manganese

This is a new solution of the 3d ed. N. F. It is made from ferric peptonate (see *Liquor Ferri Peptonati*), soluble manganese citrate, ammonia water, aromatic elixir, alcohol and distilled water. It is used as a chalybeate and alterative.

Average dose: 8 Cc. (2 fluidrachms).

LIQUOR FERRI PROTOCHLORIDI. N. F.

Solution of Protochloride of Iron [Solution of Ferrous Chloride]

This formula does not differ from that of the 2d ed. N. F. It is made from iron wire, hydrochloric acid, glycerin, diluted hypophosphorous acid and distilled water. About 20 grains of ferrous chloride are represented by 1 fluidrachm of finished solution. It is used as a chalybeate tonic.

Average dose: 0.65 Cc. (10 minims).

LIQUOR HYDRARGYRI ET POTASSII IODIDI. N. F.

Solution of Iodide of Mercury and Potassium [Solution of Potassium Iodohydrargyrate, Channing's Solution]

The formula for this solution does not differ from that of the 2d ed. N. F. It represents about 1 per cent. of red iodide of mercury and 0.8 per cent. of potassium iodide in aqueous solution. It is used as an alterative in the treatment of syphilis.

Average dose: 0.2 Cc. (3 minims).

LIQUOR HYPOPHOSPHITUM. N. F.

Solution of Hypophosphites

The formula for this solution does not differ from that of the 2d ed. N. F., except that hypophosphorous acid replaces citric acid. About 2 grains of calcium hypophosphite, $1\frac{1}{2}$ grains of sodium hypophosphite and 1 grain of potassium hypophosphite are contained in 1 fluidrachm of finished solution. It is used as an alterative and tonic.

Average dose: 4 Cc. (1 fluidrachm).

LIQUOR HYPOPHOSPHITUM COMPOSITUS. N. F.

Compound Solution of Hypophosphites

This is a new solution in the 3d ed. N. F. It is made from calcium, potassium, sodium, ferric, manganese and quinine hypophosphites, strychnine, potassium citrate, hypophosphorous acid, orange flower water, glycerin and distilled water. It is used as an alterative and tonic.

Average dose: 4 Cc. (1 fluidrachm).

LIQUOR IODI CARBOLATUS. N. F.**Carbolized Solution of Iodine****[Boulton's Solution, French Mixture]**

The formula for this solution does not differ from that of the 2d ed. N. F. It is made from compound solution of iodine, phenol, glycerin and water. It is used externally.

LIQUOR IODI CAUSTICUS. N. F.**Caustic Solution of Iodine****[Iodine Caustic, Churchill's Iodine Caustic]**

The formula for this solution does not differ from that of the 2d ed. N. F. It contains iodine, potassium iodide and water. It is used externally as a caustic and counter-irritant.

LIQUOR MAGNESII BROMIDI. N. F.**Solution of Magnesium Bromide**

The proportions of the ingredients in this solution do not differ from those in the 2d ed. N. F. The solution is made from magnesium carbonate and diluted hydrobromic acid. About $7\frac{1}{2}$ grains of magnesium bromide are contained in 1 fluidrachm of finished solution. Used as a nerve.

Average dose: 4 Cc. (1 fluidrachm).

LIQUOR MAGNESII SULPHATIS EFFERVESCENS. N. F.**Liquor Magnesiae Effervescens [Effervescent Solution of Magnesium Sulphate]**

The formula for this solution does not differ from that of the 2d ed. N. F. About 360 grains of magnesium sulphate are contained in 12 fluidounces of the finished solution. It is used as a cathartic, like solution of magnesium citrate.

Average dose: The contents of a bottle (about 12 fl. oz.).

LIQUOR MORPHINÆ CITRATIS. N. F.**Solution of Morphine Citrate**

The quantities of morphine and citric acid were very slightly increased in this solution in the 3d ed. N. F. It is made from morphine, citric acid, cochineal, alcohol and distilled water. About 2 grains of morphine in the form of citrate are contained in 1 fluidrachm of finished solution. It is used as a sedative.

Dose: 0.32 Cc. (5 minims).

LIQUOR MORPHINÆ HYPODERMICUS. N. F.**Hypodermic Solution of Morphine [Magen-die's Solution of Morphine]**

This solution of morphine should not be confounded with the U. S. Pharm. (1870) solution

of morphine, as it is 16 times as strong. Salicylic acid in small quantity is added in the 3d ed. N. F., to promote solubility. Two grains of morphine sulphate are contained in 1 fluidrachm of the finished solution. Used hypodermically as an anodyne.

Average dose: 0.32 Cc. (5 minims).

LIQUOR PANCREATICUS. N. F.**Pancreatic Solution**

The formula for this solution does not differ from that of the 2d ed. N. F. It is made from pancreatin, sodium bicarbonate, glycerin, compound spirit of cardamom, alcohol, purified tale and water. About 1 grain of pancreatin is represented in 1 fluidrachm of the finished solution. It is used as a digestive.

Average dose: 4 Cc. (1 fluidrachm).

LIQUOR PEPSINI. N. F.**Liquid Pepsin**

The formula for this solution has been changed in the 3d ed. N. F. It is now made from glycerite of pepsin, hydrochloric acid, glycerin and water. It is used as a digestive.

Average dose: 8 Cc. (2 fluidrachms).

LIQUOR PEPSINI AROMATICUS. N. F.**Aromatic Solution of Pepsin [Aromatic Liquid Pepsin]**

The formula for this solution does not differ from that of the 2d ed. N. F. It is made from pepsin, oils of cinnamon, pimenta and cloves, and alcohol, hydrochloric acid, glycerin and water. About 1 grain of pepsin is represented in 1 fluidrachm of finished solution. It is used as a digestive.

Average dose: 8 Cc. (2 fluidrachms).

LIQUOR PHOSPHATUM ACIDUS. N. F.**Acid Solution of Phosphates [Solution of Acid Phosphates]**

The title of this preparation in the 2d ed. N. F. was *Liquor Acidi Phosphorici Compositus*. No change was made in the formula in the 3d ed. It is a solution of acid phosphates made by adding sulphuric acid and water to bone ash, expressing and filtering. It is used as a tonic.

Average dose: 8 Cc. (2 fluidrachms).

LIQUOR PHOSPHORI. N. F.**Solution of Phosphorus****[Thompson's Solution of Phosphorus]**

The formula for this solution does not differ from that of the 2d ed. N. F. It is made from phosphorus, absolute alcohol, spirit of peppermint and glycerin. About 1-24th of a grain

of phosphorus is contained in 1 fluidrachm of finished solution. It is used as a tonic and stimulant in nervous diseases.

Average dose: 0.65 Cc. (10 minims).

LIQUOR PICIS ALKALINUS. N. F.

Alkaline Solution of Tar

The formula for this solution does not differ from that of the 2d ed. N. F. It contains about 25 per cent. of tar and 12.5 per cent. of potassium hydroxide in water. It is used in skin diseases as an external application.

LIQUOR POTASSÆ CHLORINATÆ. N. F.

Solution of Chlorinated Potassa

[Liquor Potassæ Chloratæ, Javelle Water]

In the Latin title in the 3d ed. N. F. the word "Chloratæ" was changed to "Chlorinatæ." The formula for this solution does not differ from that of the 2d ed. N. F. It is made from potassium carbonate, chlorinated lime and water. It is used as a disinfectant.

LIQUOR POTASSII ARSENATIS ET BROMIDI. N. F.

Solution of Potassium Arsenate and Bromide [Liquor Arseni Bromidi, Solution of Bromide of Arsenic, Clemens's Solution]

The formula for this solution differs from that of the 2d ed. N. F., the quantity of potassium bicarbonate being increased four-fold. It contains the equivalent of 1 per cent. of arsenic trioxide in the form of potassium arsenate and bromide, in 1 fluidrachm of the finished solution. It is used as an alternative and in the treatment of diabetes.

Average dose: 0.2 Cc. (3 minims).

LIQUOR SACCHARINI. N. F.

Solution of Saccharin

The formula for this solution does not differ from that of the 2d ed. N. F., except that the quantity of sodium bicarbonate is slightly increased in the 3d ed. It is used as a sweetening solution.

LIQUOR SERIPARUS. N. F.

Liquid Rennet

The formula for this solution does not differ from that of the 2d ed. N. F., except a slight variation in the proportion of alcohol and water. It is used to coagulate milk.

LIQUOR SODII ARSENATIS, PEARSON. N. F.

Pearson's Solution of Sodium Arsenate

The formula for this solution does not differ from that of the 2d ed. N. F. This preparation should not be confounded with the Liquor

Sodii Arsenatis, U. S. P., which is ten times stronger than Pearson's Solution. It contains about 1-6th per cent. of crystallized sodium arsenate or about 1-10th per cent. of anhydrous sodium arsenate. Whenever it is prescribed or dispensed, the name "Pearson" should be specified, to avoid serious mistakes. It is used as an alternative.

Average dose: 0.2 Cc. (3 minims).

LIQUOR SODII BORATIS COMPOSITUS.

N. F.

Compound Solution of Sodium Borate [Dobell's Solution]

The formula for this solution does not differ from that of the 2d ed. N. F. It contains about 1.5 per cent. each of sodium borate and sodium bicarbonate and 0.3 per cent. of phenol, with glycerin and water. It is an alkaline, antiseptic solution, to be used externally.

LIQUOR SODII CARBOLATIS. N. F.

Solution of Sodium Carbolate

The formula for this solution does not differ from that of the 2d ed. N. F. It contains 50 per cent. of phenol in combination with 3.5 per cent. of sodium hydroxide and water. It is used externally as an antiseptic. It is not to be confounded with the proprietary preparation known as "phénol sodique."

LIQUOR SODII CITRATIS. N. F.

Solution of Sodium Citrate [Mistura Sodii Citratis, Saturatio, Potio Riveri, G. P.]

The formula for this solution does not differ from that of the 2d ed. N. F. It is made with 2 per cent. of citric acid and 2.5 per cent. of sodium bicarbonate in water. Used in febrile diseases.

Average dose: 8 Cc. (2 fluidrachms).

LIQUOR SODII CITRO-TARTRATIS EFFERVESCENS. N. F.

Effervescent Solution of Sodium Citro- Tartrate [Tartro-Citric Lemonade]

The formula for this solution does not differ from that of the 2d ed. N. F., except that the proportion of water is slightly increased. It is made from sodium bicarbonate, tartaric acid, citric acid, syrup of citric acid and water. Used as a laxative.

Average dose: The contents of a bottle (containing about 12 fl. oz.).

LIQUOR SODII OLEATIS. N. F.

Solution of Sodium Oleate

The formula for this solution does not differ from that of the 2d ed. N. F. It contains about

6.25 per cent. of white castile soap dissolved in water. It is used in the preparation of oleates.

LIQUOR STRYCHNINÆ ACETATIS. N. F.

Solution of Strychnine Acetate
[Hall's Solution of Strychnine]

The formula for this solution does not differ from that of the 2d ed. N. F. This preparation should not be confounded with the Liquor Strychninæ Hydrochloridi of the British Pharmacopœia, which is much stronger. Solution of strychnine acetate is made from strychnine acetate, diluted acetic acid, alcohol, compound tincture of cardamom and water. About $\frac{1}{8}$ of a grain of strychnine acetate is contained in 1 fluidrachm of the finished solution. It is used as a cardiac stimulant and tonic.

Average dose: 0.6 Cc. (10 minims).

LIQUOR ZINCI ET ALUMINI COMPOSITUS. N. F.

Compound Solution of Zinc and Aluminum

The formula for this solution does not differ from that of the 2d ed. N. F. It contains about 20 per cent. of zinc sulphate and aluminum sulphate, with betanaphthol, oil of thyme and water. It is used externally as an astringent and disinfectant.

LIQUOR ZINCI ET FERRI COMPOSITUS. N. F.

Compound Solution of Zinc and Iron
[Deodorant Solution]

The formula for this solution does not differ from that of the 2d ed. N. F., except in the replacing of diluted hypophosphorous acid by 30 per cent. hypophosphorous acid. It contains 20 per cent. each of zinc sulphate and ferrous sulphate, 6.5 per cent. of copper sulphate, with betanaphthol, oil of thyme, hypophosphorous acid and water. It is used as an antiseptic and astringent solution.

LIQUOR ZINGIBERIS. N. F.

Solution of Ginger
[Soluble Essence of Ginger]

The formula for this solution does not differ from that of the 2d ed. N. F. It is an aqueous solution of ginger made from 33.5 per cent. of fluidextract of ginger, 10 per cent. of powdered pumice, and water. Intended to mix with water or syrup without precipitation.

Average dose: 3 Cc. (45 minims).

LOTIO ADSTRINGENS. N. F.

Astringent Lotion [Warren's Styptic]

The formula for this lotion does not differ from that of the 2d ed. N. F. It contains about

38 per cent. of sulphuric acid, 31 per cent. each of oil of turpentine and alcohol. It is used as an astringent and styptic.

LOTIO FLAVA. N. F.

Yellow Lotion
[Yellow Wash, Aqua Phagedænica Flava]

The formula for this lotion does not differ from that of the 2d ed. N. F. It contains about 0.3 per cent. of corrosive mercuric chloride in lime water slightly diluted with water. It is used externally in skin diseases.

LOTIO NIGRA. N. F.

Black Lotion
[Black Wash, Aqua Phagedænica Nigra]

In this lotion the proportion of mild mercurous chloride was increased in the 3d ed. N. F. It contains now 0.875 per cent. (formerly 0.75 per cent.) of mild mercurous chloride in lime water slightly diluted with water. It is used externally in skin diseases.

LOTIO PLUMBI ET OPII. N. F.

Lotion of Lead and Opium
[Lead and Opium Wash]

The formula for this lotion does not differ from that of the 2d ed. N. F. It contains 1.75 per cent. of lead acetate and 3.5 per cent. of tincture of opium in water. It is used as an astringent and sedative external application.

MAGMA MAGNESIÆ. N. F.

Magnesia Magma [Milk of Magnesia]

This is a new preparation in the 3d ed. N. F. It is made from magnesium sulphate, sodium hydroxide and water. About 3 grains of magnesium hydroxide are represented by 1 fluidrachm of the magma. It is used as an antacid.

Average dose: 8 Cc. (2 fluidrachms).

MISTURA ACACIÆ. N. F.

Mixture of Acacia
[Mistura Gummosa, G. P. I.]

The formula for this preparation does not differ from that of the 2d ed. N. F. It contains 7.5 per cent. each of acacia and sugar in water. It is used as a demulcent.

-MISTURA ADSTRINGENS ET ESCHAROTICA. N. F.

Astringent and Escharotic Mixture
[Villate's Solution]

The formula for this preparation does not differ from that of the 2d ed. N. F. It is made from solution of lead subacetate, copper sulphate, zinc sulphate and diluted acetic acid.

The solution is filtered from the precipitated lead sulphate. It is used externally as an astringent and escharotic.

MISTURA AMMONII CHLORIDI. N. F.

Mixture of Ammonium Chloride

[Mistura, or Mixtura, Solvens Simplex]

The formula for this mixture does not differ from that of the 2d ed. N. F. It contains 2.5 per cent. each of ammonium chloride and purified extract of glycyrrhiza in water. It is used as an expectorant.

Average dose: 8 Ce. (2 fluidrachms).

MISTURA CAMPHORÆ ACIDA. N. F.

Acid Camphor Mixture

[Mistura Antidysenterica, Hope's Mixture]

The formula for this mixture does not differ from that of the 2d ed. N. F. It contains 1.75 per cent. of nitric acid, 1.2 per cent. of tincture of opium in camphor water. It is used as an antispasmodic and astringent.

Average dose: 8 Ce. (2 fluidrachms).

MISTURA CAMPHORÆ AROMATICA. N. F.

Aromatic Camphor Mixture [Parrish's Camphor Mixture]

The formula for this mixture does not differ from that of the 2d ed. N. F. It contains 25 per cent. of compound tincture of lavender, 3.5 per cent. of sugar, and camphor water. It is used in diarrhœa as a carminative.

Average dose: 8 Ce. (2 fluidrachms).

MISTURA CARMINATIVA. N. F.

Carminative Mixture [Dalby's Carminative]

The formula for this preparation does not differ from that of the 2d ed. N. F. It is made from magnesium carbonate, potassium carbonate, tincture of opium, oils of caraway, fennel and peppermint, with syrup and water. About $\frac{1}{8}$ of a grain of opium is represented in 1 fluidrachm of the finished mixture. It is used as a carminative.

Average dose: Infants, 0.5 Ce. (8 minims).

MISTURA CHLORALI ET POTASSII BROMIDI COMPOSITA. N. F.

"Chloral and Bromide Compound"

The formula for this mixture differs from that of the 2d ed. N. F. in the reduction of the quantities of hydrated chloral and potassium bromide, the omission of tincture of quillaja and alcohol, and the introduction of powdered pumice, in order to make a more satisfactory solution. About 12 grains each of hydrated chloral and potassium bromide, and $\frac{1}{8}$ grain each of the extracts of Indian cannabis and

hyoscyamus are represented in 1 fluidrachm of the finished mixture. It is used as a sedative and hypnotic.

Average dose: 4 Ce. (1 fluidrachm).

MISTURA CHLOROFORMI ET CANNABIS INDICÆ COMPOSITA. N. F.

Compound Mixture of Chloroform and Cannabis Indica [Chloroform Anodyne]

The proportions of tinctures of Indian cannabis and capsicum were materially reduced in the 3d ed. N. F., and ether somewhat increased. It contains chloroform, ether, tincture of Indian cannabis, tincture of capsicum, morphine sulphate, oil of peppermint, glycerin, water and alcohol. About $7\frac{1}{2}$ minims of chloroform, 11 minims of tincture of Indian cannabis, 2 minims of tincture of capsicum, 1-7th of a grain of morphine sulphate, are represented in 1 fluidrachm of the finished mixture. It is used in diarrhœa and cholera.

Average dose: 2 Ce. (30 minims).

MISTURÆ CONTRA DIARRHŒAM. N. F.

Diarrhœa Mixtures

1. *Cholera Mixture.* "*Sun Mixture.*"—This mixture contains tincture of opium, tincture of capsicum, tincture of rhubarb, spirit of camphor, spirit of peppermint and alcohol.

Average dose: 2 Ce. (30 minims).

2. *Squibb's Diarrhœa Mixture.*—This mixture contains tinctures of opium and capsicum, spirit of camphor, chloroform and alcohol.

Average dose: 2 Ce. (30 minims).

3. *Loomis's Diarrhœa Mixture.*—This mixture contains tinctures of opium and rhubarb, compound tincture of gambir, oil of sassafras and compound tincture of lavender.

Average dose: 2 Ce. (30 minims).

4. *Thielmann's Diarrhœa Mixture.*—This mixture contains wine of opium, tincture of valerian, ether, oil of peppermint, fluidextract of ipecac and alcohol.

Average dose: 2 Ce. (30 minims).

5. *Velpéau's Diarrhœa Mixture.*—This mixture contains camphor, tincture of opium, and compound tincture of gambir.

Average dose: 2 Ce. (30 minims).

MISTURÆ COPAIBÆ. N. F.

Copaiba Mixtures

In the 3d ed. N. F. the word "composita" in the Latin title and the word "compound" in the English name as found in the 2d ed. N. F. does not appear.

1. *Lafayette Mixture.*—The quantities of solution of potassium hydroxide and syrup were slightly decreased in the 3d ed. N. F. in this mixture, and mucilage of acacia substituted for mucilage of dextrin. The mixture contains copaiba, spirit of nitrous ether, compound tinc-

ture of lavender, solution of potassium hydroxide, syrup, and mucilage of acacia. It is used in the treatment of gonorrhœa.

Average dose: 8 Cc. (2 fluidrachms).

2. *Chapman's Mixture*.—The quantity of tincture of opium was slightly increased (from 30 to 32 Cc.) in the 3d ed. N. F. This mixture contains copaiba, spirit of nitrous ether, compound tincture of lavender, tincture of opium, mucilage of acacia and water. Used in the treatment of gonorrhœa.

Average dose: 4 Cc. (1 fluidrachm).

MISTURA GUAIACI. N. F.

Mixture of Guaiac

The formula for this mixture does not differ from that of the 2d ed. N. F.; it contains 2.5 per cent. each of guaiac and sugar, with acacia and cinnamon water. It is used in the treatment of rheumatism.

Average dose: 16 Cc. (4 fluidrachms).

MISTURA OLEI PICIS. N. F.

Mixture of Oil of Tar

[Mistura Picis Liquidæ, Tar Mixture]

The formula for this mixture does not differ from that of the 2d ed. N. F. It contains purified extract of glycyrrhiza, oil of tar, sugar, chloroform, oil of peppermint, alcohol, and water. It is used as an expectorant.

Average dose: 8 Cc. (2 fluidrachms).

MISTURA OLEO-BALSAMICA. N. F.

Oleo-balsamic Mixture [Mistura Oleoso-balsamica, G. P.; Balsamum Vitæ Hoffmanni]

The formula for this mixture does not differ from that of the 2d ed. N. F. It contains the oils of lavender, thyme, lemon, nutmeg, orange flowers, cloves and cinnamon, with balsam of Peru and alcohol. It is used as a stimulant and carminative.

MISTURA PECTORALIS, STOKES. N. F.

[Stokes's Expectorant]

The name of this mixture was changed in the 3d ed. N. F.; it was formerly Mistura Expectorans, Stokes. Ammonia water has been added to the formula, and the quantity of water decreased. It is made from ammonium carbonate, the fluidextracts of senega and squill, camphorated tincture of opium, ammonia water, water and syrup of tolu. It is used as an expectorant.

Average dose: 4 Cc. (1 fluidrachm).

MISTURA RHEI COMPOSITA. N. F.

Compound Mixture of Rhubarb

[Squibb's Rhubarb Mixture]

The formula for this mixture does not differ from that of the 2d ed. N. F. It is made from

the fluidextracts of rhubarb and ipecac, sodium bicarbonate, glycerin and peppermint water. It is used as an antacid and laxative.

Average dose: 8 Cc. (2 fluidrachms).

MISTURA SASSAFRAS ET OPII. N. F.

Mixture of Sassafras and Opium

[Mistura Opii Alkalina, Godfrey's Cordial]

The formula for this mixture does not differ from that of the 2d ed. N. F. About 2 minims of tincture of opium are contained in 1 fluidrachm of the finished mixture. It is used as a carminative.

Average dose: Infants, 0.65 Cc. (10 minims).

MISTURA SODÆ ET MENTHÆ. N. F.

Mixture of Soda and Spearmint

[Soda Mint]

The formula for this mixture does not differ from that of the 2d ed. N. F.; it contains 5 per cent. of sodium bicarbonate, with aromatic spirit of ammonia and spearmint water. It is antacid and carminative.

Average dose: 8 Cc. (2 fluidrachms).

MISTURA SPLENETICA. N. F.

Splenetic Mixture

[Spleen Mixture, Gadberry's Mixture]

The formula for this mixture does not differ from that of the 2d ed. N. F. It is made from ferrous sulphate, quinine sulphate, nitric acid, potassium nitrate and water. It is used in malarial fever as an antiperiodic.

Average dose: 4 Cc. (1 fluidrachm).

MISTURA SULPHURICA ACIDA. N. F.

Sulphuric Acid Mixture [Mistura Sulphurica Acida, G. P.; Haller's Acid Elixir]

The formula for this mixture does not differ from that of the 2d ed. N. F. It contains 25 per cent. of sulphuric acid in alcohol. It is an antihidrotic and astringent mixture.

Average dose: 0.5 Cc. (8 minims).

MUCILAGO CHONDRI. N. F.

Mucilage of Irish Moss

The formula for this mucilage does not differ from that of the 2d ed. N. F. It contains 3 per cent. of Irish moss in water. It is used as an emulsifying agent and demulcent.

MUCILAGO DEXTRINI. N. F.

Mucilage of Dextrin

The formula for this mucilage does not differ from that of the 2d ed. N. F. It consists of 33.5 per cent. of dextrin in water, and is used in preparing emulsions.

MUCILAGO SALEP. N. F.**Mucilage of Salep**

The formula for this mucilage does not differ from that of the 2d ed. N. F. It contains about 1 per cent. of powdered salep in water. It is used as a demulcent.

OLEA INFUSA. N. F.**Infused Oils**

The formula for these is a general one. The infused oils are made from the dried herb, alcohol, ammonia water, lard oil and cotton seed oil.

OLEATUM ACONITINÆ. N. F.**Oleate of Aconitine**

The formula for this oleate does not differ from that of the 2d ed. N. F. It is a solution of 2 per cent. of aconitine in oleic acid. It should be used with care in the external treatment of neuralgia.

OLEATUM ZINCI. N. F.**Zinc Oleate**

The formula for this oleate does not differ from that of the 2d ed. N. F. It is a powder made from crystallized zinc acetate, solution of sodium oleate and water. Used externally as an astringent.

OLEOSACCHARA. N. F.**Oil-Sugars [Elæosacchara, G. P.]**

The general formula for this class of preparations does not differ from that of the 2d ed. N. F. Oil-sugars are made by triturating volatile oils with sugar, and are used as vehicles.

OLEUM CARBOLATUM. N. F.**Carbolized Oil**

The formula for this preparation does not differ from that of the 2d ed. N. F. It is made by dissolving 5 per cent. of phenol in cotton seed oil. Used externally.

OLEUM HYOSCYAMI COMPOSITUM. N. F.**Compound Oil of Hyoscyamus
[Balsamum Tranquillans]**

The formula for this oil does not differ from that of the 2d ed. N. F. It is made from the oils of absinth, lavender, rosemary, sage and thyme, with infused oil of hyoscyamus. It is used as an anodyne.

OXYMEL SCILLÆ. N. F.**Oxymel of Squill**

The formula for this preparation does not differ from that of the 2d ed. N. F. It is made from 1 part of vinegar of squill and two parts of honey. Used as an expectorant.

Average dose: 4 Cc. (1 fluidrachm).

PASTÆ DERMATOLOGICÆ. N. F.**Dermatologic Pastes**

Under this head are included formulas for seven dermatological pastes, which are new preparations in the 3d ed. N. F. They are as follows:

1. *Pasta Dextrinata*. "*Dextrinated Paste*." This is made from dextrin, glycerin and distilled water. Used as a vehicle.

2. *Pasta Ichthyoli, Unna*. "*Unna's Ichthyol Paste*."—This is made from ammonium ichthylsulphonate and dextrinated paste. Used in skin diseases.

3. *Pasta Naphtholi, Lassar*. "*Lassar's Naphthol Paste*."—This is made from betanaphthol, precipitated sulphur, petrolatum and soft soap.

4. *Pasta Resorcini Mitis, Lassar*. "*Lassar's Mild Resorcin Paste*."—This is made from resorcinol, zinc oxide, starch and liquid petrolatum.

5. *Pasta Zinci, Lassar*. "*Lassar's Zinc-Salicyl Paste*."—This is made from salicylic acid, zinc oxide, starch and white petrolatum.

6. *Pasta Zinci Mollis, Unna*. "*Unna's Soft Zinc Paste*."—This is made from zinc oxide, calcium carbonate, linseed oil and lime water.

7. *Pasta Zinci Sulfurata, Unna*. "*Unna's Sulphurated Zinc Paste*."—This is made from zinc oxide, precipitated sulphur, silicic acid and benzoinated lard.

PEPSINUM AROMATICUM. N. F.**Aromatic Pepsin**

The formula for this preparation does not differ from that of the 2d ed. N. F. It is made from saccharated pepsin (U. S. P. 1890), aromatic fluidextract, tartaric acid and sodium chloride. It is used for indigestion.

Average dose: 2 Gm. (30 grains).

**PETROLATUM SAPONATUM LIQUIDUM.
N. F.****Liquid Saponated Petrolatum
["Liquid Petrox"]**

This is a new preparation in the 3d ed. N. F. It is made from liquid petrolatum, oleic acid and spirit of ammonia, and is used as a vehicle for external application.

PETROLATUM SAPONATUM SPISSUM.

N. F.

Solid Saponated Petrolatum
[“Solid Petrox”]

This is a new preparation in the 3d ed. N. F. It is made from petrolatum, oleic acid and spirit of ammonia, and is used as a vehicle for ointments.

PILULÆ AD PRANDIUM. N. F.**Dinner Pills**

1.—The 3d ed. N. F. recommends that when dinner pills are prescribed, the official pills of aloes and mastic should be dispensed.

Dose of dinner pills, 1 or 2.

2. *Chapman's Dinner Pill*.—The formula for this pill does not differ from that of the 2d ed. N. F. Each pill contains $1\frac{1}{2}$ grains of purified aloes, $1\frac{1}{2}$ grains of mastic, 1 grain of ipecac and about $\frac{1}{4}$ minim of oil of fennel.

3. *Cole's Dinner Pill*.—The formula for this pill does not differ from that of the 2d ed. N. F. Each pill contains 1 and $\frac{1}{2}$ of a grain each of purified aloes, mass of mercury, and jalap and 1-50th of a grain of antimony and potassium tartrate.

4. *Hall's Dinner Pill*.—The formula for this pill does not differ from that of the 2d ed. N. F. Each pill contains 1 grain each of purified aloes, extract of glycyrrhiza, soap, and molasses.

PILULÆ ALOES ET PODOPHYLLI COMPOSITÆ. N. F.**Compound Pills of Aloes and Podophyllum**
[Janeway's Pills]

The formula for these pills does not differ from that of the 2d ed. N. F. Each pill contains 1 grain of purified aloes, $\frac{1}{2}$ grain resin of podophyllum, $\frac{1}{4}$ grain of extract of belladonna leaves, and $\frac{1}{4}$ of a grain of extract of nux vomica. They are used as a laxative.

PILULÆ ALOINI COMPOSITÆ. N. F.**Compound Pills of Aloin**

The formula for these pills does not differ from that of the 2d ed. N. F. Each pill contains $\frac{1}{2}$ grain of aloin, $\frac{1}{2}$ grain of resin of podophyllum, $\frac{1}{4}$ grain of extract of belladonna leaves. Cathartic.

PILULÆ ALOINI, STRYCHNINÆ ET BELLADONNÆ. N. F.**Pills of Aloin, Strychnine and Belladonna**

The formula for these pills does not differ from that of the 2d ed. N. F. Each pill contains $\frac{1}{2}$ grain of aloin, 1-120th grain of strychnine, and $\frac{1}{2}$ grain of extract of belladonna leaves. Used as a laxative and tonic.

PILULÆ ALOINI, STRYCHNINÆ ET BELLADONNÆ COMPOSITÆ. N. F.**Compound Pills of Aloin, Strychnine and Belladonna**

The formula for these pills does not differ from that of the 2d ed. N. F. Each pill contains $\frac{1}{2}$ grain of aloin, 1-120th grain of strychnine, $\frac{1}{2}$ grain of extract of belladonna leaves, and $\frac{1}{2}$ grain of extract of cascara sagrada. Used as a tonic and laxative.

PILULÆ ANTIDYSPEPTICÆ. N. F.**Antidyspeptic Pills**

The formula for these pills does not differ from that of the 2d ed. N. F. Each pill contains 1-40th grain of strychnine, 1-10th grain of ipecac, 1-10th grain of extract of belladonna leaves, 2 grains of mass of mercury, and 2 grains of compound extract of colocynth. Used as a cholagogue and tonic.

PILULÆ ANTINEURALGICÆ. N. F.**Antineuralgic Pills**

1. *Gross' Antineuralgic Pills*.—The formula for these pills does not differ from that of the 2d ed. N. F. Each pill contains 2 grains of quinine sulphate, 1-20th grain of morphine sulphate, 1-30th grain of strychnine, 1-20th grain of arsenic trioxide, and $\frac{1}{2}$ grain of extract of aconite leaves (U. S. P., 1870). Used for neuralgia.

2. *Brown Séguard's Antineuralgic (or Neuralgia) Pills*.—The formula for these pills does not differ from that of the 2d ed. N. F. Each pill contains $\frac{3}{4}$ grain of extract of hyoseyamus, $\frac{3}{4}$ grain of extract of conium, $\frac{1}{2}$ grain of extract of ignatia (U. S. P., 1870), $\frac{1}{2}$ grain of extract of opium, $\frac{1}{2}$ grain of extract of aconite leaves (U. S. P., 1870), $\frac{1}{4}$ grain of extract of Indian cannabis, $\frac{1}{2}$ grain of extract of stramonium, and 1-6th grain of extract of belladonna leaves. Used in neuralgia.

PILULÆ ANTIPERIODICÆ. N. F.**Antiperiodic Pills [Warburg's Pills]**

The formula for these pills does not differ from that of the 2d ed. N. F. Each pill contains 1 grain of extract of aloes, $\frac{1}{2}$ grain of rhubarb, $\frac{1}{2}$ grain of angelica seed, $\frac{1}{4}$ grain of elecampane, $\frac{1}{4}$ grain of saffron, $\frac{1}{4}$ grain of fennel, $\frac{1}{2}$ grain of zedoary root, $\frac{1}{2}$ grain of cubebs, $\frac{1}{2}$ grain of myrrh, $\frac{1}{2}$ grain of white agaric, $\frac{1}{2}$ grain of camphor, 1 and 2-5th grains of quinine sulphate, with a sufficient quantity of extract of gentian to form a mass.

Warburg's Pills without aloes have the same composition, except that the extract of aloes is omitted. Used as an antiperiodic.

Dose, 1 to 3 pills one to three times daily.

PILULÆ COLOCYNTHIDIS COMPOSITÆ. N. F.

Compound Pills of Colocynth [Pilulæ Coccia, Cochia Pills]

The formula for these pills does not differ from that of the 2d ed. N. F. Each pill contains 1-6th grain of extract of colocynth, 2 grains of purified aloes, 2 grains of resin of scammony and $\frac{1}{4}$ minim of oil of cloves. Used as a cathartic.

PILULÆ COLOCYNTHIDIS ET HYOSCYAMI. N. F.

Pills of Colocynth and Hyoscyamus

The formula for these pills does not differ from that of the 2d ed. N. F. Each pill contains 1-10th grain of extract of colocynth, $1\frac{1}{2}$ grains of purified aloes, $1\frac{1}{2}$ grains of resin of scammony, 1-6th minim of oil of cloves, and $1\frac{1}{2}$ grains of extract of hyoscyamus. Used as a cathartic.

PILULÆ COLOCYNTHIDIS ET PODO- PHYLLI. N. F.

Pills of Colocynth and Podophyllum

The formula for these pills does not differ from that of the 2d ed. N. F. Each pill contains $2\frac{1}{2}$ grains of compound extract of colocynth, and $\frac{1}{4}$ grain of resin of podophyllum. Used as a cathartic.

PILULÆ GLONINI. N. F.

Pills of Glonoin [Pills of Nitroglycerin]

The formula for these pills does not differ from that of the 2d ed. N. F. They are made from spirit of glyceryl trinitrate, althæa and confection of rose. Each pill contains 1-100th grain of nitroglycerin. Used as a cardiac stimulant.

PILULÆ LAXATIVÆ POST PARTUM. N. F.

Laxative Pills after Confinement [Barker's Post Partum Pills]

The formula for these pills does not differ from that of the 2d ed. N. F. Each pill contains $1\frac{1}{2}$ grains of compound extract of colocynth, 5-6th grain of purified aloes, 5-12th grain of extract of nux vomica, 1-12th grain of resin of podophyllum, 1-12th grain of ipecac, and $1\frac{1}{4}$ grains of extract of hyoscyamus. Used as a cathartic.

PILULÆ METALLORUM. N. F.

Metallic Pills [Pilulæ Metallorum Amaræ, Bitter Metallic Pills]

The formula for these pills does not differ from that of the 2d ed. N. F. Each pill con-

tains 1 grain of reduced iron, 1 grain of quinine sulphate, 1-20th grain of strychnine, and 1-20th grain of arsenic trioxide. Used as a tonic.

Aitken's Tonic Pills are somewhat weaker, each pill containing $\frac{3}{4}$ grain of reduced iron, 1 grain of quinine sulphate, 1-50th grain of strychnine, and 1-50th grain of arsenic trioxide. Used as a tonic.

PILULÆ OPII ET CAMPHORÆ. N. F.

Pills of Opium and Camphor

The formula for these pills does not differ from that of the 2d ed. N. F. Each pill contains 1 grain of powdered opium and 2 grains of camphor. Used as an anodyne and astringent.

PILULÆ OPII ET PLUMBI. N. F.

Pills of Opium and Lead

The formula for these pills does not differ from that of the 2d ed. N. F. Each pill contains 1 grain of powdered opium and 1 grain of lead acetate. Used as an anodyne and astringent.

PILULÆ QUADRUPLICES. N. F.

Quadruplex Pills [Quatuor Pills, Pilulæ Ferri et Quininæ Compositæ]

The formula for these pills does not differ from that of the 2d ed. N. F. Each pill contains 1 grain each of dried ferrous sulphate, quinine sulphate, purified aloes, with $\frac{1}{4}$ grain of extract of nux vomica, and sufficient extract of gentian to form a mass. Used as a tonic and laxative.

PILULÆ TRIPLICES. N. F.

Triplex Pills [Pilula Triplex]

1.—The formula for these pills does not differ from that of the 2d ed. N. F. Each pill contains 2 grains of purified aloes, 1 grain of mass of mercury and $\frac{1}{4}$ grain of resin of podophyllum. Used as a cathartic and cholagogue.

2. *Francis' Triplex Pill*.—The formula for these pills does not differ from that of the 2d ed. N. F. Each pill contains 5-6th grain of purified aloes, 5-6th grain of scammony, 5-6th grain of mass of mercury, 1-20th minim of croton oil, $\frac{1}{4}$ minim of oil of caraway, and sufficient tincture of aloes and myrrh to form a mass. Used as a cathartic.

PULVIS ACACIÆ COMPOSITUS. N. F.

Compound Powder of Acacia [Pulvis Gummosus, G. P.]

The formula for this powder does not differ from that of the 2d ed. N. F., except in the substitution of parts for grammes. It contains

50 per cent. of powdered acacia, 34 per cent. of powdered glycyrrhiza, and 16 per cent. of powdered sugar.

PULVIS ALOES ET CANELLÆ. N. F.

Powder of Aloes and Canella

["Hiera Picra"]

The formula for this powder does not differ from that of the 2d ed. N. F., except in the substitution of parts for grammes. It contains 80 per cent. of purified aloes and 20 per cent. of powdered canella. It is used as an emmenagogue and laxative.

Average dose: 1 Gm. (15 grains).

PULVIS AMYGDALÆ COMPOSITUS. N. F.

Compound Powder of Almond

The formula for this powder does not differ from that of the 2d ed. N. F., except in the substitution of parts for grammes. It contains 60 per cent. of sweet almond, 30 per cent. of powdered sugar and 10 per cent. of powdered acacia. It is used for extemporaneously preparing emulsion of almond.

PULVIS ANTICATARRHALIS. N. F.

Catarrh Powder [Catarrh Snuff]

The formula for this powder does not differ from that of the 2d ed. N. F. It contains 75 grammes of bismuth subnitrate, 25 grammes of powdered acacia and 0.41 gramme of morphine hydrochloride. It is used for catarrh.

PULVIS ANTISEPTICUS. N. F.

Soluble Antiseptic Powder [Pulvis Antisepticus Solubilis]

This is a new preparation in the 3d ed. N. F. It contains salicylic acid, phenol, eucalyptol, menthol, thymol, zinc sulphate and powdered boric acid. It is used as a dusting powder.

PULVIS CATECHU COMPOSITUS. N. F.

Compound Powder of Catechu

The formula for this powder does not differ from that of the 2d ed. N. F., except in the substitution of parts for grammes. It contains 40 per cent. of powdered gambir, 20 per cent. of powdered kino, 20 per cent. of powdered krameria, 10 per cent. of powdered cinnamon, and 10 per cent. of powdered nutmeg. It is used in diarrhœa.

Average dose: 1.30 Gm. (20 grains).

PULVIS CRETÆ AROMATICUS. N. F.

Aromatic Powder of Chalk

The formula for this powder does not differ from that of the 2d ed. N. F., except in the substitution of parts for grammes. It contains

8 per cent. of cinnamon, 6 per cent. each of saffron and nutmeg, 3 per cent. of cloves, 2 per cent. of cardamom, 23 per cent. of prepared chalk and 52 per cent. of sugar. It is used in diarrhœa.

Average dose: 2 Gm. (30 grains).

PULVIS CRETÆ AROMATICUS CUM OPIO. N. F.

N. F.

Aromatic Powder of Chalk with Opium

The formula for this powder does not differ from that of the 2d ed. N. F., except in the substitution of parts for grammes. One grain of powdered opium and 39 grains of aromatic powder of chalk are contained in 40 grains of this preparation. It is used as a sedative and astringent.

Average dose: 1 Gm. (15 grains).

PULVIS FERRI ET QUININÆ CITRATIS EFFERVESCENS. N. F.

Effervescent Powder of Citrate of Iron and Quinine [Effervescent Citrate of Iron and Quinine]

The formula for this powder does not differ from that of the 2d ed. N. F., except in the substitution of parts for grammes. It is made from soluble citrate of iron and quinine, saccharated sodium bicarbonate and saccharated tartaric acid. About 1 grain of soluble citrate of iron and quinine is represented by 90 grains of the powder. It is used as a chalybeate and tonic.

Average dose: 6 Gm. (90 grains).

PULVIS FERRI PHOSPHATIS EFFERVESCENS. N. F.

Effervescent Powder of Ferric Phosphate [Effervescent Phosphate of Iron]

The formula for this powder does not differ from that of the 2d ed. N. F., except that the word "soluble" is now added to the words ferric phosphate, and in the substitution of parts for grammes. It contains soluble ferric phosphate, saccharated sodium bicarbonate and saccharated tartaric acid. About 2 grains of soluble ferric phosphate are contained in 90 grains of the powder. Used as a chalybeate.

Average dose: 6 Gm. (90 grains).

PULVIS HYDRARGYRI CHLORIDI MITIS ET JALAPÆ. N. F.

Powder of Mild Chloride of Mercury and Jalap [Calomel and Jalap]

The formula for this powder does not differ from that of the 2d ed. N. F., except in the substitution of parts for grammes. It contains

34 per cent. of mild chloride of mercury and 66 per cent. of jalap. It is cathartic and cholagogue.

Average dose: 0.65 Gm. (10 grains).

PULVIS IODOFORMI COMPOSITUS. N. F.

Compound Powder of Iodoform

["Naphthalin Iodoform"]

The formula for this powder does not differ from that of the 2d ed. N. F., except in the substitution of parts for grammes. It contains 20 per cent. of powdered iodoform, 30 per cent. of powdered boric acid, 50 per cent. of powdered naphthalene, with a little oil of bergamot. Used as an antiseptic.

PULVIS KINO COMPOSITUS. N. F.

Compound Powder of Kino

The formula for this powder does not differ from that of the 2d ed. N. F., except in the substitution of parts for grammes. It contains 75 per cent. of powdered kino, 5 per cent. of powdered opium and 20 per cent. of powdered cinnamon. Used as an astringent.

Average dose: 1 Gm. (15 grains).

PULVIS MYRICÆ COMPOSITUS. N. F.

Compound Powder of Bayberry

[Composition Powder]

The formula for this powder does not differ from that of the 2d ed. N. F., except in the substitution of parts for grammes. It contains 60 per cent. of bayberry bark, 30 per cent. of ginger, 5 per cent. of capsicum and 5 per cent. of cloves. It is used as a carminative and stimulant.

Average dose: 1 Gm. (15 grains).

PULVIS PANCREATICUS COMPOSITUS.

N. F.

Compound Pancreatic Powder

[Peptonizing Powder]

The formula for this powder does not differ from that of the 2d ed. N. F., except in the substitution of parts for grammes. It contains 20 per cent. of pancreatin and 80 per cent. of sodium bicarbonate. Twenty-five grains of this powder are sufficient to peptonize 1 pint of fresh cow's milk. Used as a digestive.

PULVIS PEPSINI COMPOSITUS. N. F.

Compound Powder of Pepsin

[Pulvis Digestivus]

The formula for this powder does not differ from that of the 2d ed. N. F. It contains saccharated pepsin, pancreatin, diastase, lactic acid, hydrochloric acid and sugar of milk. Used as a digestive.

Average dose: 1 Gm. (15 grains).

PULVIS POTASSII BROMIDI EFFERVES- CENS. N. F.

Effervescent Powder of Potassium Bromide [Effervescent Potassium Bromide]

The formula for this powder does not differ from that of the 2d ed. N. F., except in the substitution of parts for grammes. It contains potassium bromide, saccharated sodium bicarbonate and saccharated tartaric acid. About 10 grains of potassium bromide are contained in 90 grains of finished powder. It is used as a nerve sedative.

Average dose: 6 Gm. (90 grains).

PULVIS POTASSII BROMIDI EFFERVES- CENS CUM CAFFEINA. N. F.

Effervescent Powder of Potassium Bromide with Caffeine [Effervescent Potassium Bromide with Caffeine]

The formula for this powder does not differ from that of the 2d ed. N. F., except in the substitution of parts for grammes. It contains potassium bromide, caffeine, saccharated sodium bicarbonate, saccharated tartaric acid. About 10 grains of potassium bromide and 1 grain of caffeine are contained in 90 grains of the finished powder. Used as a nerve sedative.

Average dose: 6 Gm. (90 grains).

PULVIS PRO LACTE HUMANISATO. N. F.

Humanizing Milk Powder ["Milk Powder"]

This is a new powder in the 3d ed. N. F. It contains 3.5 per cent. of compound pancreatic powder and 96.5 per cent. of powdered sugar of milk. This powder is intended to be used in preparing humanized milk.

PULVIS RHEI ET MAGNESIÆ ANISATUS.

N. F.

Anisated Powder of Rhubarb and Magnesia [Compound Anise Powder]

The formula for this powder does not differ from that of the 2d ed. N. F. It contains 35 per cent. of powdered rhubarb and 65 per cent. of heavy magnesia, with oil of anise and alcohol. It is laxative and carminative.

Average dose: Infants, 0.3 Gm. (5 grains).

PULVIS SALIS CAROLINI FACTITII EFFER- VESCENS. N. F.

Effervescent Powder of Artificial Carlsbad Salt [Effervescent Artificial Carlsbad Salt]

The formula for this powder does not differ from that of the 2d ed. N. F., except in the substitution of parts for grammes. It contains artificial Carlsbad salt, saccharated sodium bicarbonate and saccharated tartaric acid. Ninety

grains of this powder dissolved in 6 fluidounces of water represents an equal volume of Carlsbad water (Sprudel). Used as a laxative.

Average dose: 6 Gm. (90 grains).

**PULVIS SALIS KISSINGENSIS FACTITII
EFFERVESCENS. N. F.**

Effervescent Powder of Artificial Kissingen Salt [Effervescent Artificial Kissingen Salt]

The formula for this powder does not differ from that of the 2d ed. N. F., except in the substitution of parts for grammes. It contains artificial Kissingen salt, saccharated sodium bicarbonate, and saccharated tartaric acid. Eighty grains of this powder dissolved in 6 fluidounces of water represents an equal volume of Kissingen water (Rakoczi). It is an alternative.

Average dose: 5.5 Gm. (80 grains).

**PULVIS SALIS VICHYANI FACTITII EFFER-
VESCENS. N. F.**

Effervescent Powder of Artificial Vichy Salt [Effervescent Artificial Vichy Salt]

The formula for this powder does not differ from that of the 2d ed. N. F., except in the substitution of parts for grammes. It contains artificial Vichy salt, saccharated sodium bicarbonate and saccharated tartaric acid. Fifty-seven grains of this powder dissolved in 6 fluidounces of water represents an equal volume of Vichy water (Grande Grille). It is an antacid.

Average dose: 3.75 Gm. (57 grains).

**PULVIS SALIS VICHYANI FACTITII EFFER-
VESCENS CUM LITHIO. N. F.**

Effervescent Powder of Artificial Vichy Salt with Lithium [Effervescent Artificial Vichy Salt with Lithium]

The formula for this powder does not differ from that of the 2d ed. N. F., except in the substitution of parts for grammes. It contains artificial Vichy salt, lithium citrate, saccharated sodium bicarbonate and saccharated tartaric acid. Ninety grains of this powder represent about 14 grains of artificial Vichy salt and 5 grains of lithium citrate. It is antacid and antilithic.

Average dose: 6 Gm. (90 grains).

PULVIS TALCI SALICYLICUS. N. F.
Salicylated Powder of Talcum

The formula for this powder does not differ from that of the 2d ed. N. F., except in the substitution of parts for grammes. It contains 3

per cent. of salicylic acid, 10 per cent. of boric acid and 87 per cent. of talc, all in very fine powder. Used as an antiseptic dusting powder.

SAL CAROLINUM FACTITIUM. N. F.
Artificial Carlsbad Salt

1. *In a dry, amorphous form (G. P.).*—The formula for this salt does not differ from that of the 2d ed. N. F., except in the substitution of parts for grammes. It contains 2 per cent. of potassium sulphate, 18 per cent. of sodium chloride, 36 per cent. of sodium bicarbonate, and 44 per cent. of dried sodium sulphate. Sixteen grains of this salt when dissolved in 6 fluidounces of water represent an equal volume of Carlsbad water (Sprudel). Used as a laxative.

2. *In a crystalline form.*—The formula for this variety of artificial Carlsbad salt does not differ from that of the 2d ed. N. F., except in the substitution of parts for grammes. It is made from 2 parts of potassium sulphate, 18 parts of sodium chloride, 61 parts of sodium carbonate in clear crystals, 88 parts of crystallized sodium sulphate and 50 parts of distilled water. Twenty-seven grains of this salt dissolved in 6 fluidounces of water represent an equal volume of Carlsbad water (Sprudel). It is a laxative.

SAL KISSINGENSE FACTITIUM. N. F.
Artificial Kissingen Salt

The formula for this salt does not differ from that of the 2d ed. N. F., except in the substitution of parts for grammes. It is made from 1.7 parts of potassium chloride, 35.7 parts of sodium chloride, 5.9 parts of magnesium sulphate (anhydrous), and 10.7 parts of sodium bicarbonate. Twenty-four grains of this salt dissolved in 6 fluidounces of water represents an equal volume of Kissingen water (Rakoczi). It is an antacid.

SAL VICHYANUM FACTITIUM. N. F.
Artificial Vichy Salt

The formula for this preparation does not differ from that of the 2d ed. N. F., except in the substitution of parts for grammes. It contains sodium bicarbonate, potassium carbonate, magnesium sulphate (anhydrous) and sodium chloride. Fourteen grains dissolved in 6 fluidounces of water represents an equal volume of Vichy water (Grande Grille). It is antacid.

SODA CUM CALCE. N. F.
Soda with Lime [London Paste]

The formula for this preparation does not differ from that of the 2d ed. N. F. It is made from equal parts of sodium hydroxide and lime. Used as a caustic externally.

SODII BICARBONAS SACCHARATUS. N. F.**Saccharated Sodium Bicarbonate**

The formula for this preparation does not differ from that of the 2d ed. N. F., except in the substitution of parts for grammes. It is made from 3 parts of sodium bicarbonate and 1 part of sugar. Used for making effervescent powders.

SODII BORO-BENZOAS. N. F.**Sodium Boro-Benzoate**

The formula for this preparation does not differ from that of the 2d ed. N. F. It is made from 3 parts of sodium borate and 4 parts of sodium benzoate. Used as an antiseptic, and in urinary affections.

SPECIES EMOLLIENTES. N. F.**Emollient Species [Emollient Cataplasma, G. P.]**

The formula for this preparation does not differ from that of the 2d ed. N. F. It is made from equal parts of althæa leaves, mallow leaves, melilot tops, matricaria and flaxseed. Emollient; used for making an emollient poultice.

SPECIES LAXANTES. N. F.**Laxative Species [St. Germain Tea, G. P.]**

The formula for this preparation does not differ from that of the 2d ed. N. F. It contains 16 parts of cut senna, 10 parts of elder flowers, 5 parts of bruised fennel, 5 parts of bruised anise and 4 parts of potassium bistratrate. Used as a laxative.

SPECIES PECTORALES. N. F.**Pectoral Species [Species ad Infusum Pectorale, Breast Tea, G. P.]**

The formula for this preparation does not differ from that of the 2d ed. N. F. It contains 9 parts of althæa, peeled, 4 parts of colts-foot leaves, 3 parts of Russian glycyrrhiza, peeled, and 1 part of orris root. Used as a pectoral.

SPIRITUS ACIDI FORMICI. N. F.**Spirit of Formic Acid [Spiritus Formicarum, G. P.; Spirit of Ants]**

The formula for this spirit does not differ from that of the 2d ed. N. F. It contains 3.5 per cent. of formic acid in alcohol and distilled water. Used externally as a counter-irritant.

SPIRITUS AROMATICUS. N. F.**Aromatic Spirit**

The formula for this spirit does not differ from that given in the 2d ed. N. F. This prep-

aration contains 6.5 per cent. of compound spirit of orange in alcohol. It is used only for flavoring purposes.

SPIRITUS CARDAMOMI COMPOSITUS. N. F.**Compound Spirit of Cardamom**

The formula for this spirit does not differ from that of the 2d ed. N. F. It is made from the oils of cardamom, caraway and cinnamon dissolved in alcohol, glycerin and water. Used for flavoring, being equivalent to compound tincture of cinnamon, without the coloring matter.

SPIRITUS CURASSAO. N. F.**Spirit of Curacao**

The formula for this spirit does not differ from that of the 2d ed. N. F. It is made from oils of Curaçao orange, fennel and bitter almond with alcohol. Used for flavoring.

SPIRITUS OPHTHALMICUS. N. F.**Ophthalmic Spirit [Alcoholic Eye-Wash]**

The formula for this spirit does not differ from that of the 2d ed. N. F. It contains 2 per cent. of oil of lavender, 6 per cent. of oil of rosemary, and 92 per cent. of alcohol. Used as an eye wash.

SPIRITUS PHOSPHORI. N. F.**Spirit of Phosphorus [Tincture of Phosphorus]**

This spirit is identical with the Spirit of Phosphorus of the U. S. Pharmacopœia (1890). There is a slight change, however, in the form of the apparatus.

Average dose: 0.5 Cc. (8 minims).

SPIRITUS SAPONATUS. N. F.**Spirit of Soap**

The formula for this spirit does not differ from that of the 2d ed. N. F. It contains 17.5 per cent. of Castile soap in shavings, with alcohol and water. Used as a detergent.

SPIRITUS SINAPIS. N. F.**Spirit of Mustard**

The formula for this spirit does not differ from that of the 2d ed. N. F. It contains 2 per cent. of volatile oil of mustard in alcohol. Used as a counter-irritant.

SPONGIA COMPRESSA. N. F.**Compressed Sponge [Sponge Tent]**

The formula for this does not differ from that of the 2d ed. N. F. It consists of sponge treated with diluted mucilage of acacia and dried. Used for surgical purposes.

SPONGIA DECOLORATA. N. F.**Decolorized Sponge [Bleached Sponge]**

The formula for this does not differ from that of the 2d ed. N. F. It consists of sponge bleached by treatment with potassium permanganate, sodium thiosulphate, hydrochloric acid and water. Used for surgical purposes.

SUCCUS LIMETTÆ CUM PEPSINO. N. F.**Lime Juice and Pepsin**

In the Latin title for this preparation the word "Limettæ" replaces the word "Limonis" of the 2d ed. N. F. The formula was also changed in the 3d ed. It is now made from 40 per cent. of glycerite of pepsin and 60 per cent. of lime juice. Used in dyspepsia.

Average dose: 8 Cc. (2 fluidrachms).

SUPPOSITORIA BOROGLYCERINI. N. F.**Suppositories of Boroglycerin**

This is a new preparation in the 3d ed. N. F. The suppositories contain glycerinated gelatin, boric acid, glycerin and water.

STILI DILUBILES. N. F.**Paste Pencils ["Unna Pencils"]**

This is a new class of preparations introduced into the 3d ed. N. F., and consists of pencils suggested by Dr. Unna. They are used in dermatological practice.

1. *Stilus Acidæ Salicylicæ Dilubilis, 10 per cent.*—*Salicylic Acid Pencil (10 per cent.)*. These pencils contain 10 per cent. of salicylic acid, with tragacanth, starch, dextrin, sugar and distilled water.

2. *Stilus Cocainæ Dilubilis, 5 per cent.*—*Cocaine Pencil (5 per cent.)*.—These pencils contain 5 per cent. of cocaine hydrochloride, with tragacanth, starch, dextrin, sugar and distilled water.

SYRUPUS ACTÆÆ COMPOSITUS. N. F.**Compound Syrup of Actæa [Compound Syrup of Cimicifuga, or Black Cohosh]**

The formula for this syrup does not differ from that of the 2d ed. N. F. It is made from the fluidextracts of cimicifuga, glycyrrhiza, senega and ipecac, with wild cherry, purified talc, sugar and water. It is used as an antispasmodic.

Average dose: 4 Cc. (1 fluidrachm).

SYRUPUS ASARI COMPOSITUS. N. F.**Compound Syrup of Asarum [Compound Syrup of Canada Snake-Root]**

The formula for this syrup was slightly changed in the 3d ed. N. F., the quantities of asarum, alcohol and sugar having been reduced.

It is made from asarum root, alcohol, cochineal, potassium carbonate, wine of ipecac, sugar and water. About 3.5 grains of asarum are represented by 1 fluidrachm of finished syrup. Used as a stimulant and expectorant.

Average dose: 4 Cc. (1 fluidrachm).

SYRUPUS BROMIDORUM. N. F.**Syrup of the Bromides**

This is a new preparation in the 3d ed. N. F. It is made from potassium, sodium, ammonium, calcium and lithium bromides, tincture of vanilla, compound tincture of eudbear, compound syrup of sarsaparilla and syrup. About 15 grains of the mixed bromides are contained in 1 fluidrachm of the finished syrup. Used as a nervous sedative.

Average dose: 4 Cc. (1 fluidrachm).

SYRUPUS CALCII CHLORHYDROPHOSPHATIS. N. F.**Syrup of Calcium Chlorhydrophosphate [Syrup of Chlorhydrophosphate of Lime]**

The formula for this syrup does not differ from that of the 2d ed. N. F. It is made from precipitated calcium phosphate, tincture of lemon peel, hydrochloric acid, water and syrup. About 1 grain of calcium phosphate is contained in 1 fluidrachm of the finished syrup. Used as an alternative.

Average dose: 4 Cc. (1 fluidrachm).

SYRUPUS CALCII ET SODII HYPOPHOSPHITUM. N. F.**Syrup of Calcium and Sodium Hypophosphites [Syrup of Hypophosphite of Lime and Soda]**

The formula for this syrup does not differ from that of the 2d ed. N. F., except in the replacing of citric acid with hypophosphorous acid. About 2 grains each of calcium and sodium hypophosphites, with hypophosphorous acid, sugar and water, are contained in 1 fluidrachm of the finished syrup. Used as an alternative.

Average dose: 4 Cc. (1 fluidrachm).

SYRUPUS CALCII HYPOPHOSPHITIS. N. F.**Syrup of Calcium Hypophosphite [Syrup of Hypophosphite of Lime]**

The formula for this syrup does not differ from that of the 2d ed. N. F., except in the substitution of hypophosphorous acid for citric acid. It is made from calcium hypophosphite, hypophosphorous acid, sugar and water. About 2 grains of calcium hypophosphite are contained in 1 fluidrachm of the finished syrup. Used as an alternative.

Average dose: 4 Cc. (1 fluidrachm).

SYRUPUS CALCII IODIDI. N. F.**Syrup of Calcium Iodide**

The formula for this syrup does not differ from that of the 2d ed. N. F. It is made from iodine, iron wire, precipitated calcium carbonate, sugar, distilled water and syrup. About 5 grains of calcium iodide are contained in 1 fluidrachm of the finished syrup.

Average dose: 2 Cc. (30 minims).

SYRUPUS CALCII LACTOPHOSPHATIS CUM FERRO. N. F.**Syrup of Calcium Lactophosphate with Iron**
[Syrup of Lactophosphate of Lime with Iron]

The formula for this syrup does not differ from that of the 2d ed. N. F. It is made from ferrous lactate, potassium citrate, water and syrup of calcium lactophosphate. About $\frac{1}{2}$ grain of ferrous lactate and $\frac{1}{4}$ grain of calcium lactate are contained in 1 fluidrachm of the finished syrup. Used as an alternative and tonic.

Average dose: 4 Cc. (1 fluidrachm).

SYRUPUS CHONDRI COMPOSITUS. N. F.**Compound Syrup of Chondrus** [Compound Syrup of Irish Moss]

The formula for this syrup does not differ from that of the 2d ed. N. F. It is made from Irish moss, the fluidextracts of ipecac, squill and senega, camphorated tincture of opium, purified talc, sugar and water. Used as an expectorant.

Average dose: 8 Cc. (2 fluidrachms).

SYRUPUS CINNAMOMI. N. F.**Syrup of Cinnamon**

In the formula for this syrup in the 3d ed. N. F. the quantity of sugar has been increased and Saigon cinnamon replaces the Cassia of the 2d ed. It is made from Saigon cinnamon, alcohol, sugar and cinnamon water. It is used for flavoring.

Average dose: 4 Cc. (1 fluidrachm).

SYRUPUS CODEINÆ. N. F.**Syrup of Codeine**

The formula for this syrup does not differ from that of the 2d ed. N. F. It is made from codeine sulphate and syrup. About $\frac{1}{4}$ grain of codeine sulphate is contained in 1 fluidrachm of the finished syrup. Used as a sedative.

Average dose: 2 Cc. (30 minims).

SYRUPUS COFFÆ. N. F.**Syrup of Coffee**

The formula for this syrup was slightly changed in the 3d ed. N. F., by increasing the

quantity of sugar. It is made from roasted coffee, sugar and water. About 25 per cent. of coffee is represented in this syrup. Used as a stimulant.

Average dose: 8 Cc. (2 fluidrachms).

SYRUPUS ERIODICTYI AROMATICUS. N. F.**Aromatic Syrup of Eriodictyon** [Aromatic Syrup of Yerba Santa, Syrupus Corrigenis]

The formula for this syrup does not differ from that of the 2d ed. N. F. It is made from fluidextract of eriodictyon, solution of potassium hydroxide, compound tincture of cardamom, the oils of sassafras, lemon and cloves, alcohol, sugar and water. Used as a vehicle and as an alternative.

Average dose: 8 Cc. (2 fluidrachms).

SYRUPUS FERRI ARSENATIS. N. F.**Syrup of Arsenate of Iron**

A slight change was made in the formula for this preparation. It is now made from dried sodium arsenate, ferric citrate, water and syrup. About 1-40th grain of ferric arsenate is contained in 1 fluidrachm of the finished syrup. Used as an alternative and tonic.

Average dose: 0.5 Cc. (8 minims).

SYRUPUS FERRI CITRO-IODIDI. N. F.**Syrup of Citro-Iodide of Iron** [Tasteless Syrup of Iodide of Iron]

The English name of the syrup was changed from Syrup of Ferric Citro-Iodide to Syrup of Citro-Iodide of Iron in the 3d ed. N. F. The quantities of the ingredients were also slightly changed. It is made from iodine, iron wire, potassium citrate, sugar and distilled water. An amount of iron corresponding to about 4 grains of ferric iodide is contained in 1 fluidrachm of the finished syrup. It is alternative and tonic.

Average dose: 2 Cc. (30 minims).

SYRUPUS FERRI ET MANGANI IODIDI. N. F.**Syrup of Iodide of Iron and Manganese**

The formula of this syrup was slightly changed. It is made from iodine, iron wire, manganese sulphate, potassium iodide, sugar and water. About 6 grains of ferrous iodide and $2\frac{1}{4}$ grains of manganese iodide are contained in 1 fluidrachm of finished syrup. Used as an alternative.

Average dose: 1 Cc. (15 minims).

SYRUPUS FERRI HYPOPHOSPHITIS. N. F.**Syrup of Ferric Hypophosphite**

The formula for this syrup does not differ from that of the 2d ed. N. F. It is made from

ferric hypophosphite, potassium citrate, orange flower water and syrup. About 1 grain of ferric hypophosphite is contained in 1 fluidrachm of the finished syrup. Used as a tonic.

Average dose: 4 Cc. (1 fluidrachm).

SYRUPUS FERRI LACTOPHOSPHATIS. N. F.

Syrup of Lactophosphate of Iron

The quantity of water was very slightly increased in the 3d ed. N. F. The syrup is made from ferrous lactate, phosphoric acid, water and syrup. About 1 grain of ferrous lactate or about $1\frac{1}{2}$ grains of so-called lactophosphate of iron is represented in 1 fluidrachm of the finished syrup. Used as an alternative.

Average dose: 4 Cc. (1 fluidrachm).

SYRUPUS FERRI PROTOCHLORIDI. N. F.

Syrup of Protochloride of Iron [Syrup of Ferrous Chloride]

The formula for this syrup does not differ from that of the 2d ed. N. F. It is made from solution of ferrous chloride, glycerin, orange flower water and syrup. About 1 grain of ferrous chloride is contained in 1 fluidrachm of the finished syrup. Used as a tonic.

Average dose: 4 Cc. (1 fluidrachm).

SYRUPUS FERRI SACCHARATI SOLUBILIS. N. F.

Syrup of Soluble Saccharated Iron [Syrupus Ferri Oxydati Solubilis, G. P.; Syrup of Saccharated Oxide of Iron, Syrup of Soluble Oxide of Iron]

The formula for this syrup does not differ from that of the 2d ed. N. F. It is made from solution of ferric chloride, sodium hydroxide, solution of sodium hydroxide, sugar, distilled water and syrup. About 1 grain of metallic iron is represented in 75 minims of this syrup. Used as a tonic and chalybeate.

Average dose: 4 Cc. (1 fluidrachm).

SYRUPUS GLYCYRRHIZÆ. N. F.

Syrup of Glycyrrhiza [Syrup of Licorice]

The formula for this syrup does not differ from that of the 2d ed. N. F. It is made from pure extract of glycyrrhiza, glycerin, sugar and water. About 30 grains of glycyrrhiza root are represented in 1 fluidrachm of the finished syrup. It is used as a vehicle.

Average dose: 8 Cc. (2 fluidrachms).

SYRUPUS HYDROCHLOROPHOSPHATUM. N. F.

Compound Syrup of Phosphates with Quinine and Strychnine ["Compound Syrup of Hydrochlorophosphates"]

This is a new preparation of the 3d ed. N. F., and is made from potassium bicarbonate, mag-

nesium carbonate, calcium carbonate, soluble ferric phosphate, quinine hydrochloride, strychnine sulphate, phosphoric acid, citric acid, orange flower water, glycerin, sugar and distilled water. It contains 1-128th grain of strychnine sulphate and $\frac{1}{4}$ grain of quinine hydrochloride in 1 fluidrachm of finished syrup. Used as a tonic.

Average dose: 4 Cc. (1 fluidrachm).

SYRUPUS IPECACUANHÆ ET OPII. N. F.

Syrup of Ipecac and Opium [Syrup of Dover's Powder]

This syrup is of the same relative strength as that of the 2d ed. N. F. Instead of being made as it was formerly, with fluidextract of ipecac and tincture of deodorized opium, it is now made with the official tincture of ipecac and opium, with spirit of cinnamon, cinnamon water and syrup. Five grains of Dover's powder are represented by 1 fluidrachm of finished syrup. Used as a diaphoretic and sedative.

Average dose: 4 Cc. (1 fluidrachm).

SYRUPUS MANNÆ. N. F.

Syrup of Manna

The formula for this syrup does not differ from that of the 2d ed. N. F. It contains about 12.5 per cent. of manna, with sugar, alcohol and water. Used as a laxative.

Average dose: 8 Cc. (2 fluidrachms).

SYRUPUS MORPHINÆ COMPOSITUS. N. F.

Compound Syrup of Morphine

The formula for this syrup does not differ from that of the 2d ed. N. F. It is made from the fluidextracts of ipecac, senega and rhubarb, morphine sulphate, oil of sassafras and syrup. About 1-32d grain of morphine sulphate is contained in 1 fluidrachm of the finished syrup. Used as a sedative and expectorant.

Average dose: 4 Cc. (1 fluidrachm).

SYRUPUS MORPHINÆ SULPHATIS. N. F.

Syrup of Morphine Sulphate [Syrupus Morphinæ, Syrup of Morphine]

This preparation does not differ from that of the 2d ed. N. F. It is made from morphine sulphate, water and syrup. About $\frac{1}{8}$ grain of morphine sulphate is contained in 1 fluidrachm of the finished syrup.

Care should be used in dispensing this syrup, as the Sirop de Morphine of the French Codex is a weaker preparation and contains about 1-25th grain of morphine hydrochloride in 1 fluidrachm of syrup. Used as a sedative.

Average dose: 2 Cc. (30 minims).

SYRUPUS PAPAVERIS. N. F.**Syrup of Poppy**

The formula for this syrup does not differ from that of the 2d ed. N. F. It contains 87.5 per cent. of tincture of poppy, with sugar and water. It is a mild anodyne.

Average dose: 2 Cc. (30 minims).

SYRUPUS PECTORALIS. N. F.**Pectoral Syrup [Jackson's Pectoral (or Cough) Syrup]**

The formula for this syrup does not differ from that of the 2d ed. N. F. It is made from morphine hydrochloride, oil of sassafras and syrup of acacia. About 1-32d grain of morphine hydrochloride is contained in 1 fluidrachm of the finished syrup. It is pectoral and sedative.

Average dose: 4 Cc. (1 fluidrachm).

SYRUPUS PHOSPHATUM COMPOSITUS. N. F.**Compound Syrup of Phosphates ["Chemical Food"]**

Several changes were made in the formula for this syrup. The quantity of citric acid was considerably increased, and that of glycerin has been increased five times; the quantity of phosphoric acid was slightly increased. The syrup is made from precipitated calcium carbonate, soluble ferric phosphate, ammonium phosphate, potassium bicarbonate, sodium bicarbonate, citric acid, glycerin, phosphoric acid, orange flower water, tincture of eudbear, sugar and water. About 2 grains of calcium phosphate, 1 grain each of the phosphates of iron and ammonium and smaller quantities of potassium and sodium phosphates are contained in 1 fluidrachm of the finished syrup. It is used as a tonic and nutrient.

Average dose: 4 Cc. (1 fluidrachm).

SYRUPUS PINI STROBI COMPOSITUS. N. F.**Compound Syrup of White Pine**

The formula for this syrup does not differ from that of the 2d ed. N. F., except that the quantities of white pine bark and wild cherry bark have been slightly increased. It is made from white pine bark, wild cherry bark, spike-nard root, balm of gilead buds, sanguinaria root, sassafras bark, morphine sulphate, chloroform, sugar, alcohol, water and syrup. About 1-32d grain of morphine sulphate is contained in 1 fluidrachm of the finished syrup. Used as an expectorant and sedative.

Average dose: 4 Cc. (1 fluidrachm).

SYRUPUS QUINIDINÆ. N. F.**Syrup of Quinidine [Bitterless Syrup of Quinidine]**

This is a new preparation of the 3d ed. N. F. It is made from quinidine, mucilage of acacia,

solution of saccharin, and syrup of orange flowers. About $\frac{1}{2}$ grain of quinidine is contained in 1 fluidrachm of finished syrup. Used as a tonic and antiperiodic.

Average dose: 4 Cc. (1 fluidrachm).

SYRUPUS RHAMNI CATHARTICÆ. N. F.**Syrup of Rhamnus Cathartica [Syrup of Buckthorn Berries, Syrupus Spinæ Cervinæ]**

The formula for this syrup does not differ from that of the 2d ed. N. F. It contains 20 per cent. of fermented juice of blackberries with sugar. Used as a cathartic.

Average dose: 8 Cc. (2 fluidrachms).

SYRUPUS RHEI ET POTASSII COMPOSITUS. N. F.**Compound Syrup of Rhubarb and Potassa [Neutralizing Cordial]**

The proportions of the ingredients of this syrup have been slightly changed. It is made from the fluidextracts of rhubarb and hydrastis, potassium carbonate, tincture of cinnamon, spirit of peppermint, syrup and diluted alcohol. Used as a cathartic.

Average dose: 4 Cc. (1 fluidrachm).

SYRUPUS RUBI AROMATICUS. N. F.**Aromatic Syrup of Blackberry**

The formula for this syrup was slightly changed in the 3d ed. N. F. It is made from rubus, cinnamon, nutmeg, cloves, allspice, sugar, diluted alcohol and fresh blackberry juice. It is used in diarrhoea.

Average dose: 8 Cc. (2 fluidrachms).

SYRUPUS SANGUINARIÆ. N. F.**Syrup of Sanguinaria [Syrup of Bloodroot]**

The formula for this syrup does not differ from that of the 2d ed. N. F. It is made from powdered sanguinaria, acetic acid, sugar and water. Used as an expectorant.

Average dose: 2 Cc. (30 minims).

SYRUPUS SENNÆ AROMATICUS. N. F.**Aromatic Syrup of Senna**

The formula for this syrup does not differ from that of the 2d ed. N. F., except a slight increase in the quantity of sugar. It is made from fluidextract of senna, with jalap, rhubarb, cinnamon, cloves, nutmeg, oil of lemon, sugar, and diluted alcohol. About $7\frac{1}{2}$ grains of deodorized senna, 3 grains of jalap, and 1 grain of rhubarb are contained in 1 fluidrachm of finished syrup. Used as a purgative.

Average dose: 8 Cc. (2 fluidrachms).

SYRUPUS SENNÆ COMPOSITUS. N. F.**Compound Syrup of Senna**

The formula for this syrup does not differ from that of the 2d ed. N. F., except that the quantity of alcohol is slightly increased. It is made from the fluidextracts of senna, rhubarb and frangula, oil of gaultheria, alcohol and syrup. About 8 grains of senna and 2 grains each of rhubarb and frangula are represented in 1 fluidrachm of the finished syrup. Used as a purgative.

Average dose: 8 Cc. (2 fluidrachms).

SYRUPUS SODII HYPOPHOSPHITIS. N. F.**Syrup of Sodium Hypophosphite**

The formula for this syrup does not differ from that of the 2d ed. N. F., except that hypophosphorous acid replaces citric acid. It is made from sodium hypophosphite, hypophosphorous acid, sugar and water. Two grains of sodium hypophosphite are represented by 1 fluidrachm of finished syrup. Used as an alternative.

Average dose: 4 Cc. (1 fluidrachm).

SYRUPUS STILLINGIÆ COMPOSITUS. N. F.**Compound Syrup of Stillingia.**

The formula for this syrup does not differ from that of the 2d ed. N. F., except a slight increase in the quantity of sugar. It is made from compound fluidextract of stillingia, purified talc, sugar and water. About 15 minims of compound fluidextract of stillingia are represented by 1 fluidrachm of the finished syrup. Used as an alternative.

Average dose: 4 Cc. (1 fluidrachm).

TINCTURA ACONITI, FLEMING. N. F.**Fleming's Tincture of Aconite**

The formula for this tincture does not differ from that of the 2d ed. N. F. Made from aconite root and alcohol. This is a preparation which should no longer be prescribed or dispensed, as it will be likely to produce confusion and possibly serious consequences. It is 7 times stronger than the official tincture of aconite. Seventy grammes of aconite root are represented in 100 Cc. of finished tincture. It is a heart sedative.

Average dose: 0.06 Cc. (1 minim).

TINCTURA AMARA. N. F.**Bitter Tincture [Stomachic Tincture, Bitter Stomachic Drops, Stomach Drops]**

The formula for this tincture was very slightly changed in the 3d ed. N. F., the quantities of orange berries and zedoary being increased. It is made from gentian, centaury herb, bitter orange peel, orange berries, zedoary root, alcohol and water. It is a bitter tonic.

Average dose: 2 Cc. (30 minims).

TINCTURA ANTACRIDA. N. F.**Antacid Tincture [Dysmenorrhœa Mixture, Fenner's Guaiac Mixture]**

The quantities of guaiac, Canada turpentine and oil of sassafras were slightly increased in the 3d ed. N. F. in this tincture. It is made from corrosive mercuric chloride, guaiac, Canada turpentine, oil of sassafras and alcohol. About $\frac{1}{2}$ grain of corrosive mercuric chloride is contained in 1 fluidrachm of finished tincture. Used in dysmenorrhœa.

Average dose: 1 Cc. (15 minims).

TINCTURA ANTIPERIODICA. N. F.**Antiperiodic Tincture ["Warburg's Tincture"]**

The formula for this tincture has been considerably changed, prepared chalk, opium, black pepper, cinnamon and ginger having been added in the 3d ed. N. F., to the long list of other ingredients. The proportions have also been slightly changed. It is made from rhubarb, angelica seed, elecampane, saffron, fennel, prepared chalk, gentian, zedoary, cubeb, myrrh, camphor, white agaric, opium, black pepper, cinnamon, ginger, quinine sulphate, alcohol and distilled water. About 9 gr. of quinine sulphate are contained in 1 fl. oz. of finished tincture.

The above tincture without aloes is intended to be used as a stock tincture, Warburg's tincture with aloes being made by adding 8 grains of extract of aloes to each fluidounce of Warburg's tincture. For prescription and dispensing purposes, Warburg's tincture with aloes is to be dispensed when Warburg's tincture, without specification, is ordered.

Dosage.—The dosage of Warburg's Tincture depends on the kind used—whether with aloes or without—and the intended purpose, and varies from 4 Cc. (1 fluidrachm) to 16 Cc. (4 fluidrachms). The larger quantity is given when Dr. Warburg's original directions are followed for administering the remedy in remittent fevers, which were as follows: "One-half ounce to be given alone without dilution, after the bowels have been evacuated by any convenient purgative, all drink being withheld. After three hours, another half ounce is to be given." It is an antiperiodic.

TINCTURA AROMATICA. N. F.**Aromatic Tincture**

The formula for this tincture does not differ from that of the 2d ed. N. F. It is made from cinnamon, ginger, galangal, cloves, cardamom, alcohol and water. Used as a stimulant and aromatic.

Average dose: 2 Cc. (30 minims).

TINCTURA CAPSICI ET MYRRHÆ. N. F.**Tincture of Capsicum and Myrrh [Hot Drops]**

The formula for this tincture does not differ from that of the 2d ed. N. F. It is made from capsicum, myrrh, alcohol and water. It is a powerful stimulant and carminative.

Average dose: 2 Cc. (30 minims).

TINCTURA CINCHONÆ DETANNATA. N. F.**Detannated Tincture of Cinchona**

The formula for this tincture does not differ from that of the 2d ed. N. F. It is made from fluidextract of cinchona, alcohol, solution of ferric sulphate, ammonia water, water and diluted alcohol. It is to be used in place of the official tincture of cinchona when iron preparations are directed.

Average dose: 4 Cc. (1 fluidrachm).

TINCTURA COTO. N. F.**Tincture of Coto**

The formula for this tincture does not differ from that of the 2d ed. N. F. It is made from coto bark and alcohol. Used as an astringent.

Average dose: 4 Cc. (1 fluidrachm).

TINCTURA CRESOLI SAPONATA. N. F.**Saponated Tincture of Cresol**

This is a new tincture made from 35 per cent. of cresol and 45 per cent. of soft soap with alcohol. Used as an antiseptic.

TINCTURA FERRI CHLORIDI ÆTHEREA. N. F.**Ethereal Tincture of Ferric Chloride [Bestucheff's Tincture, Lamotte's Drops]**

The formula for this tincture does not differ from that of the 2d ed. N. F. It is made from solution of ferric chloride, ether and alcohol. It should be remembered that the official solution of ferric chloride has been reduced in strength. About $\frac{1}{2}$ grain of metallic iron is represented in 1 fluidrachm of finished tincture. Used as a chalybeate.

Average dose: 4 Cc. (1 fluidrachm).

TINCTURA FERRI CITRO-CHLORIDI. N. F.**Tincture of Citro-Chloride of Iron [Tasteless Tincture of Ferric Chloride, Tasteless Tincture of Iron]**

The proportions of solution of ferric chloride and sodium citrate have been changed to conform to the alteration in strength of the official solution of ferric chloride. About $7\frac{1}{2}$ grains of dry ferric chloride are represented in 1 fluidrachm of finished tincture. Used as a chalybeate.

Average dose: 0.65 Cc. (10 minims).

TINCTURA FERRI POMATA. N. F.**Tincture of Ferrated Extract of Apples [Tinctura Ferri Malatis Crudi, Tincture of Crude Malate of Iron]**

The formula for this tincture does not differ from that of the 2d ed. N. F. It is made from ferrated extract of apples, alcohol and cinnamon water. About $\frac{1}{3}$ grain of metallic iron is represented in 1 fluidrachm of finished tincture. Used as a chalybeate.

Average dose: 4 Cc. (1 fluidrachm).

TINCTURA GUAIACI COMPOSITA. N. F.**Compound Tincture of Guaiac [Dewees' Tincture of Guaiac]**

The formula for this tincture does not differ from that of the 2d ed. N. F., except a slight increase in the quantities of pimenta and pumice. It is made from guaiac, potassium carbonate, pimenta, pumice, alcohol, water and diluted alcohol. About $7\frac{1}{2}$ grains of guaiac are represented in 1 fluidrachm of finished tincture. Used for rheumatism, and as an emmenagogue.

Average dose: 4 Cc. (1 fluidrachm).

TINCTURA IODI, CHURCHILL. N. F.**Churchill's Tincture of Iodine**

The formula for this tincture does not differ from that of the 2d ed. N. F. It is made from iodine, potassium iodide, water and alcohol. About 16.5 per cent. of iodine and 3.3 per cent. of potassium iodide are represented in the finished tincture. Used as a discutient and counter-irritant.

TINCTURA IODI DECOLORATA. N. F.**Decolorized Tincture of Iodine**

The formula for this tincture does not differ from that of the 2d ed. N. F. It is made from iodide, sodium thiosulphate, water, stronger ammonia water and alcohol. Used as a discutient.

TINCTURA JALAPÆ. N. F.**Tincture of Jalap**

The formula for this tincture does not differ from that of the 2d ed. N. F. It contains 20 per cent. of jalap, with alcohol and water. Used as a cathartic.

Average dose: 4 Cc. (1 fluidrachm).

TINCTURA JALAPÆ COMPOSITA. N. F.**Compound Tincture of Jalap**

The formula for this tincture does not differ from that of the 2d ed. N. F. It is made from 12.5 per cent. of jalap and 3.2 per cent. of scammony, with alcohol and water. Used as a purgative.

Average dose: 4 Cc. (1 fluidrachm).

TINCTURA KINO COMPOSITA. N. F.**Compound Tincture of Kino**

The quantity of tincture of kino has been doubled to conform to the reduced strength of the official tincture of kino; the quantity of cochineal has been slightly decreased. The tincture is made from the tinctures of kino and opium, spirit of camphor, oil of cloves, cochineal, aromatic spirit of ammonia and diluted alcohol. About $\frac{1}{2}$ grain each of kino and powdered opium are contained in 1 fluidrachm of finished tincture. Used as an astringent and anodyne.

Average dose: 4 Cc. (1 fluidrachm).

TINCTURA PAPAVERIS. N. F.**Tincture of Poppy**

The formula for this tincture does not differ from that of the 2d ed. N. F. It is made from poppy capsules, glycerin, alcohol and water. About 30 grains of poppy capsules, freed from seeds, are represented in 1 fluidrachm of finished tincture. Used as a sedative.

Average dose: 2 Cc. (30 minims).

TINCTURA PECTORALIS. N. F.**Pectoral Tincture [Guttæ Pectorales, Pectoral Drops, Bateman's Pectoral Drops]**

The formula for this tincture does not differ materially from that of the 2d ed. N. F. It is made from tincture of opium, compound tincture of gambir, spirit of camphor, oil of anise, caramel and diluted alcohol. About 2.5 minims of tincture of opium are represented in 1 fluidrachm of finished tincture. Used as an expectorant.

Average dose: Infants, 0.65 Cc. (10 minims).

TINCTURA PERSIONIS. N. F.**Tincture of Cudbear**

The formula for this tincture does not differ from that of the 2d ed. N. F. It is made from cudbear, alcohol and water. Used as a bright red coloring agent.

TINCTURA PERSIONIS COMPOSITA. N. F.**Compound Tincture of Cudbear**

The formula for this tincture does not differ from that of the 2d ed. N. F., except that the quantity of cudbear was slightly reduced. It is made from cudbear, caramel, alcohol and water. Used as a brownish-red coloring agent.

TINCTURA PIMPINELLÆ. N. F.**Tincture of Pimpinella**

The formula for this tincture does not differ from that of the 2d ed. N. F. It contains 16.5 per cent. of pimpinella, with alcohol and water. Used as a diuretic and tonic.

Average dose: 4 Cc. (1 fluidrachm).

TINCTURA RHEI AQUOSA. N. F.**Aqueous Tincture of Rhubarb**

The formula for this tincture was very slightly changed in the 3d ed. N. F. It is made from rhubarb, sodium borate, potassium carbonate, cinnamon water, alcohol and water. About $5\frac{3}{4}$ grains of rhubarb are represented in 1 fluidrachm of finished tincture. Used as a cathartic.

Average dose: 4 Cc. (1 fluidrachm).

TINCTURA RHEI ET GENTIANÆ. N. F.**Tincture of Rhubarb and Gentian**

The formula for this tincture does not differ from that of the 2d ed. N. F. It is made from rhubarb, gentian and diluted alcohol. About 4 grains of rhubarb and 1 grain of gentian are represented by 1 fluidrachm of finished tincture. Used as a tonic and laxative.

Average dose: 4 Cc. (1 fluidrachm).

TINCTURA RHEI VINOSA. N. F.**Vinous Tincture of Rhubarb**

The formula for this tincture does not differ from that of the 2d ed. N. F. It is made from the fluidextracts of rhubarb and bitter orange peel, tincture of cardamom, sugar and sherry wine. Used as a laxative and stomachic.

Average dose: 4 Cc. (1 fluidrachm).

TINCTURA SAPONIS VIRIDIS COMPOSITA. N. F.**Compound Tincture of Green Soap**

The formula for this tincture does not differ from that of the 2d ed. N. F. It is made from soft soap, oil of cade and alcohol. It is a detergent used in skin diseases.

TINCTURA TOLUTANA ÆTHEREA. N. F.**Ethereal Tincture of Tolu**

This is a new preparation in the 3d ed. N. F. It contains 16.5 per cent. of balsam of tolu in alcohol and ether. It is used for coating pills.

TINCTURA TOLUTANA SOLUBILIS. N. F.**Soluble Tincture of Tolu**

The formula for this tincture does not differ from that of the 2d ed. N. F. It is made from balsam of tolu, magnesium carbonate, glycerin, water and alcohol. Used for producing a transparent mixture with water or syrup.

Average dose: 2 Cc. (30 minims).

TINCTURA VANILLINI COMPOSITA. N. F.**Compound Tincture of Vanillin [Compound Essence of Vanillin]**

The formula for this tincture does not differ from that of the 2d ed. N. F. It is made from

vanillin, eumarin, alcohol, glycerin, syrup, compound tincture of eudbear and water. Used for flavoring.

TINCTURA VIBURNI OPULI COMPOSITA. N. F.

Compound Tincture of Viburnum

The formula for this tincture does not differ from that of the 2d ed. N. F. It is made from viburnum opulus, dioscorea, scullcap, cloves, cinnamon, glycerin, alcohol and water. Used as an antispasmodic.

Average dose: 4 Cc. (1 fluidrachm).

TINCTURA ZEDOARIÆ AMARA. N. F.

Bitter Tincture of Zedoary [Compound Tincture of Zedoary]

The formula for this tincture does not differ from that of the 2d ed. N. F. About 15 grains of zedoary, 7.5 grains of aloes, 3.75 grains each of rhubarb, gentian, white agaric and saffron, with glycerin, alcohol and water, are contained in 1 fluidrachm of finished tincture. It is used as a tonic and laxative.

Average dose: 4 Cc. (1 fluidrachm).

TINCTURÆ ÆTHEREÆ. N. F.

Ethereal Tinctures

In the general formula for ethereal tinctures the quantity of drug has been reduced from 12.5 per cent. to 10 per cent.

UNGUENTA EXTENSA. N. F.

"Salve Mulls" [Steatina, Steatins]

These are new preparations for external use introduced into the 3d ed. N. F., consisting of mulls or gauze upon which certain ointments are spread uniformly. The following ointments are used:

1. *Unguentum Zinci Extensum, 10 per cent. Zinc Salve Mull (10 per cent.).*—This contains 10 per cent. of zinc oxide, with benzoinated suet and benzoinated lard.

2. *Unguentum Salicylatum Extensum, 10 per cent.—Salicylic Acid Salve Mull (10 per cent.).* This contains 10 per cent. of salicylic acid with benzoinated suet and benzoinated lard.

3. *Unguentum Hydrargyri Chloridi Corrosivi Extensum, 0.2 per cent.—Corrosive Mercuric Chloride Salve Mull (0.2 per cent.).*—This contains 0.2 per cent. of corrosive mercuric chloride with alcohol, benzoinated suet and benzoinated lard.

4. *Unguentum Creosoti Salicylatum Extensum, 20 : 10 per cent.—Creosote-Salicylic Acid Salve Mull (20 : 10 per cent.).*—This contains 20 per cent. of creosote, 10 per cent. of salicylic acid, with yellow wax and benzoinated suet.

UNGUENTUM CALAMINÆ. N. F.

Calamine Ointment [Unguentum Zinci Carbonatis (Impuri), Unguentum Calaminare, Turner's Cerate]

The formula for this ointment does not differ from that of the 2d ed. N. F., except in the substitution of parts for grammes. It contains 1 part of calamine, with 5 parts of ointment. Used as an antiseptic.

UNGUENTUM CAMPHORÆ. N. F.

Camphor Ointment [Unguentum Camphoratum.

The formula for this ointment does not differ from that of the 2d ed. N. F., except in the substitution of parts for grammes. It contains 22 per cent. of camphor, with white wax and lard. Used as an anodyne.

UNGUENTUM FUSCUM. N. F.

Brown Ointment [Unguentum Matris, Mother's Salve]

The formula for this ointment does not differ from that of the 2d ed. N. F., except in the substitution of parts for grammes. It contains 50 per cent. of camphorated brown plaster, with olive oil and suet. Used as a discutient.

UNGUENTUM PICIS COMPOSITUM. N. F.

Compound Tar Ointment.

The formula for this ointment differs very little from that of the 2d ed. N. F., except in the substitution of parts for grammes. It is made from oil of tar, tincture of benzoin, zinc oxide, yellow wax, lard and cotton seed oil. It is used against parasites and in skin diseases.

UNGUENTUM RESORCINI COMPOSITUM. N. F.

Compound Resorcin Ointment ["Soothing Ointment"]

This is a new preparation in the 3d ed. N. F. It contains 6 per cent. each of resorcinol, zinc oxide and bismuth subnitrate, 12 per cent. of oil of cade, with paraffin, petrolatum and hydrous wool fat. It is used as an antiseptic and astringent in skin diseases.

UNGUENTUM SULPHURIS COMPOSITUM. N. F.

Compound Sulphur Ointment [Wilkinson's Ointment, Hebra's Itch Ointment]

The formula for this ointment does not differ from that of the 2d ed. N. F., except in the substitution of parts for grammes. It contains

10 per cent. of precipitated calcium carbonate, 15 per cent. of sublimed sulphur, 15 per cent. of oil of cade, with soft soap and lard. Used in the treatment of itch.

VINUM AURANTII. N. F.

Wine of Orange

The formula for this wine does not differ from that of the 2d ed. N. F. It is made from oil of bitter orange, alcohol, purified tale and sherry wine. Used as a flavor.

VINUM AURANTII COMPOSITUM. N. F.

Compound Wine of Orange [Elixir Aurantium Compositum, Compound Elixir of Orange]

The formula for this wine was very slightly changed in the 3d ed. N. F. The quantities of cinnamon and gentian were increased. It is made from bitter orange peel, absinthium, menyanthes leaves, cascarilla, cinnamon, gentian, potassium carbonate and sherry wine. Used as a tonic.

Average dose: 4 Cc. (1 fluidrachm).

VINUM CARNIS. N. F.

Wine of Beef ["Beef and Wine"]

The quantity of extract of beef has been slightly reduced in the 3d ed. N. F. and the quantity of hot water slightly increased. Syrup, alcohol and compound spirit of orange have been added, which, with sherry wine, completes the list of ingredients. Two grains of extract of beef are represented in 1 fluidrachm of the finished wine. Used as a nutrient tonic.

Average dose: 8 Cc. (2 fluidrachms).

VINUM CARNIS ET FERRI. N. F.

Wine of Beef and Iron ["Beef, Wine and Iron"]

Compound spirit of orange, alcohol and syrup have been added to the formula for this wine, and there has also been a slight decrease in strength. Two grains of extract of beef, and 2 minims of tincture of citro-chloride of iron are represented in 1 fluidrachm of the finished wine. Used as a nutrient and tonic.

Average dose: 8 Cc. (2 fluidrachms).

VINUM CARNIS, FERRI ET CINCHONÆ. N. F.

Wine of Beef, Iron and Cinchona ["Beef, Wine, Iron and Cinchona"]

The formula for this wine has been changed. It is now made from quinine sulphate, cinchoni-

dine sulphate, citric acid and wine of beef and iron. Two grains of extract of beef, 2 minims of tincture of citro-chloride of iron, and small quantities of cinchona alkaloids are represented in 1 fluidrachm of finished wine. Used as a tonic.

Average dose: 4 Cc. (1 fluidrachm).

VINUM COCÆ AROMATICUM. N. F.

Aromatic Wine of Coca [Vinum Erythroxyli Aromaticum, Aromatic Wine of Erythroxylin]

The formula for this wine does not differ from that of the 2d ed. N. F. It is made from fluidextract of coca, compound elixir of taraxacum, syrup of coffee, port wine, aromatic elixir and sherry wine. About 30 grains of coca are represented in 1 fluidounce of finished wine. Used as a nerve stimulant.

Average dose: 8 Cc. (2 fluidrachms).

VINUM FRAXINI AMERICANÆ. N. F.

Wine of White Ash

The formula for this wine does not differ from that of the 2d ed. N. F. About 30 grains of white ash bark are represented in 1 fluidrachm of the finished wine. Used as a stimulant and emmenagogue.

Average dose: 4 Cc. (1 fluidrachm).

VINUM PEPSINI. N. F.

Wine of Pepsin ["Pepsin Wine"]

The formula for this wine was changed in the 3d ed. N. F. It is now made from glycerite of pepsin, alcohol and sherry wine. One grain of pepsin is represented in 1 fluidrachm of the finished wine. Used as a digestive.

Average dose: 8 Cc. (2 fluidrachms).

VINUM PICIS. N. F.

Wine of Tar

The formula for this wine does not differ from that of the 2d ed. N. F. It is made from tar, water, pumice and stronger white wine (U. S. P. 1880). Used as a stimulant and expectorant.

Average dose: 8 Cc. (2 fluidrachms).

VINUM PRUNI VIRGINIANÆ. N. F.

Wine of Wild Cherry

The formula for this wine does not differ from that of the 2d ed. N. F., except that the quantity of alcohol was increased 25 per cent.

About 15 grains of wild cherry are represented in 1 fluidrachm of the finished wine. Used as a tonic and pectoral.

Average dose: 4 Cc. (1 fluidrachm).

VINUM PRUNI VIRGINIANÆ FERRATUM.
N. F.

Ferrated Wine of Wild Cherry

The formula for this wine does not differ from that of the 2d ed. N. F., except that the quantity of tincture of citro-chloride of iron was slightly decreased. About 5 minims of

tincture of citro-chloride of iron and 13½ grains of wild cherry are represented by 1 fluidrachm of finished wine. Used as a chalybeate tonic.

Average dose: 4 Cc. (1 fluidrachm).

ZINCI OLEO-STEARAS. N. F.

Oleo-Stearate of Zinc

This is a new preparation in the 3d ed. N. F. It is made from zinc acetate, stearic acid, oleic acid, potassium hydroxide, alcohol and distilled water. It is a white powder, used as an anti-septic application.

 Ellixir of buckthorn, 1787
 Ellixir of caffeine, 1784
 Ellixir of calcium bromide, 1784
 Ellixir of calcium hypophosphite, 1784
 Ellixir of calcium lactophosphate, 1784
 Ellixir of calisaya and hypophosphites, 1785
 Ellixir of calisaya and iron, 1784
 Ellixir of calisaya, ferrated, 1784
 Ellixir of calisaya, iron and bismuth, 1785
 Ellixir of calisaya, iron and lactophosphate of lime, 1785
 Ellixir of calisaya, iron and pepsin, 1785
 Ellixir of calisaya, iron and strychnine, 1785
 Ellixir of calisaya, iron, bismuth and strychnine, 1785
 Ellixir of calisaya, pepsin and strychnine, 1785
 Ellixir of cascara sagrada, 1790
 Ellixir of cascara sagrada, compound, 1790
 Ellixir of celery, compound, 1783
 Ellixir of chloroform, compound, 1784
 Ellixir of cinchona, 1784
 Ellixir of cinchona and hypophosphites, 1785
 Ellixir of cinchona and iron, 1784
 Ellixir of cinchona from alkaloids, 1784
 Ellixir of cinchona, iron and bismuth, 1785
 Ellixir of cinchona, iron, bismuth and strychnine, 1785
 Ellixir of cinchona, iron and calcium lactophosphate, 1785
 Ellixir of cinchona, iron and pepsin, 1785
 Ellixir of cinchona, iron and strychnine, 1785
 Ellixir of cinchona, pepsin and strychnine, 1785
 Ellixir of coca, 373, 1785
 Ellixir of coca and guarana, 1785
 Ellixir of corydalis, compound, 1785
 Ellixir of crampbark, compound, 1791
 Ellixir of curaçao, 1786
 Ellixir of damiana, 1791
 Ellixir of eriodictyon, aromatic, 1786
 Ellixir of erythroxylon, 1785
 Ellixir of erythroxylon and guarana, 1785
 Ellixir of eucalyptus, 1786
 Ellixir of euonymus, 1786
 Ellixir of frangula, 570, 1787
 Ellixir of gentian, 1787

- Elixir of gentian and phosphate of iron, 1787
 Elixir of gentian, ferrated, 1787
 Elixir of gentian, ferrophosphated, 1787
 Elixir of gentian, glycerinized, 1787
 Elixir of gentian with tincture of chloride of iron, 1787
 Elixir of glycerophosphates, 1788
 Elixir of glycyrrhiza, 1787
 Elixir of glycyrrhiza, aromatic, 1787
 Elixir of grindella, 1788
 Elixir of guarana, 1788
 Elixir of hops, 1788
 Elixir of humulus, 1788
 Elixir of hypophosphite of iron, 1786
 Elixir of hypophosphites, 1788
 Elixir of hypophosphites with iron, 1788
 Elixir of iron, quinine and strychnine, 1787
 Elixir of iron, quinine and strychnine phosphates, 434
 Elixir of jaborandi, 1789
 Elixir of lactate of iron, 1786
 Elixir of licorice, 1787
 Elixir of licorice, aromatic, 1787
 Elixir of lithium bromide, 1788
 Elixir of lithium citrate, 1788
 Elixir of lithium salicylate, 1788
 Elixir of malt and iron, 1788
 Elixir of monobromated camphor (note), 280
 Elixir of orange (note), 435
 Elixir of orange, compound, 1821
 Elixir of paraldehyde, 1789
 Elixir of pepsin, 1789
 Elixir of pepsin and bismuth, 1789
 Elixir of pepsin and iron, 1789
 Elixir of pepsin, bismuth and strychnine, 1789
 Elixir of pepsin, compound, 1786
 Elixir of phosphate of iron, 1786
 Elixir of phosphorus, 936 (note), 1789
 Elixir of phosphorus and nuxvomica, 1789
 Elixir of pilocarpus, 1789
 Elixir of potassium acetate, 1789
 Elixir of potassium acetate and juniper, 1790
 Elixir of potassium bromide, 1790
 Elixir of pyrophosphate of iron, 1786
 Elixir of pyrophosphate of iron, quinine and strychnine, 1786
 Elixir of quinine and phosphates, compound, 1790
 Elixir of quinine, compound, 1784
 Elixir of quinine valerianate and strychnine, 1790
 Elixir of rhamnus purshiana, 1790
 Elixir of rhubarb, 1790
 Elixir of rhubarb and magnesia, 1790
 Elixir of rhubarb and magnesium acetate, 1790
 Elixir of salicylic acid, 1783
 Elixir of sodium bromide, 1790
 Elixir of sodium hypophosphite, 1791
 Elixir of sodium salicylate, 1791
 Elixir of stillingia, compound, 1791
 Elixir of strychnine valerianate, 1791
 Elixir of tar, compound, 1789
 Elixir of taraxacum, compound, 1791
 Elixir of terpin hydrate, 1791
 Elixir of terpin hydrate with codeine, 1791
 Elixir of terpin hydrate with hewoïne, 1791
 Elixir of turnera, 1791
 Elixir of viburnum opulus, compound, 1791
 Elixir of viburnum prunifolium, 1792
 Elixir of vitriol, 75
 Elixir of wahoo, 1786
 Elixir of yerba santa, aromatic, 1786
 Elixir of zinc valerianate, 1789
 Elixir, Mynsicht's, 75
 Elixir paraldehydi, 1789
 Elixir paregoricum, 1281
 Elixir parégorique, 1281
